(Received 27 March 2002; published 16 August 2002)

By using techniques of unitarized chiral perturbation theory, where the $\Lambda(1405)$ and $\Lambda(1670)$ resonances are dynamically generated, we evaluate the magnetic moments of these resonances and their transition magnetic moment. The results obtained here differ appreciably from those obtained with existing quark models.

The width for the $\Lambda(1670)\rightarrow\Lambda(1405)\gamma$ transition is also evaluated, leading to a branching ratio of the order of $2 \times 10^{-6}$.

I. INTRODUCTION

The evaluation of static properties of baryonic resonances, like the magnetic moment, is a standard exercise when one has a wave function for the states. This is the case of the quark models where a thorough investigation of magnetic moments and other static properties [1], such as masses and couplings to the $\pi N$ system [2], has been done.

The introduction of unitary chiral techniques has allowed one to show that the octet of the lowest energy $J^P=1/2^-$ baryonic resonances can be generated dynamically from the lowest order chiral Lagrangian and by the use of natural size cutoffs or regularizing scales to make the divergent loop integrals finite. These findings allow one to classify those states as quasibound meson baryon states or, equivalently, ordinary multiple scattering resonances in coupled channels. The $\Lambda(1405)$ was one of the first resonances to receive attention from the chiral unitary perspective [3–5]. The $N^*(1535)$ was also generated within chiral unitary schemes in [6–8] and has been recently revised in [9] with the inclusion of $\pi\pi N$ channels. Recently the $\Lambda(1670)$ and $\Sigma(1620)$ [10] and the $\Xi(1620)$ states [11] have also been obtained within the same scheme, thus completing the octet of dynamically generated states.

The chiral unitary approach, or unitarized chiral perturbation theory (χPT), uses the same chiral Lagrangians as chiral perturbation theory (χPT), but makes use of unitarity in coupled channels which provides the imaginary part of the inverse of the scattering amplitude independently of the dynamics of the problem. Since $\text{Im} \, T^{-1}$ is given by unitarity, it is most natural to expand $\text{Re} \, T^{-1}$ in powers of the momentum, rather than $T$, which is done in χPT. This is the essence of the inverse amplitude method which was used with one channel in [12] and generalized to coupled channels in [13,14]. The method automatically enlarges the radius of convergence of the series expansion with respect to χPT and provides the meson resonances up to 1.2 GeV. The basics of this new series expansion is the same as in the effective range formula in quantum mechanics, except that the series expansion in the meson meson interaction is done in powers of $p^2$ rather than in the momentum of the particle moving in a potential [15]. This gives us a hint of the merit of this expansion, since, after years, the effective range formula has remained as the standard low energy expansion of the scattering matrix in quantum mechanics.

The interest of this new approach goes beyond the fact that it gives a good reproduction of the data up to much higher energies than χPT. The method also allows one to distinguish between dynamically generated and genuine resonances. What makes this distinction possible is the finding of the work [16], commonly known as resonance saturation hypothesis, that the terms in the second order Lagrangian of Gasser and Leutwyler [17] can be obtained from the exchange of, essentially, vector mesons. These vector mesons are assumed to be genuine states of QCD, in the sense that they would remain in the theory in the limit of large $N_c$. On the other hand, in [18] it was found that, by explicitly allowing the exchange of the bare vector meson resonances and scalar meson resonances and unitarizing the problem by means of the $N/D$ method, the fit to the data demanded a clear coupling of the bare vector mesons to the meson meson states while the coupling of the bare scalar mesons was compatible with zero. Yet the scalar resonances were nevertheless generated in the unitary scheme, which implied the resummation of a subseries of infinite loops. Since the loops are subleading in the large $N_c$ counting, these states would disappear in the limit of large $N_c$, distinguishing them from the genuine states which would still remain in the same limit. Hence, this would justify the name of dynamically generated mesons by the multiple scattering of the mesons implied in the unitarized scattering matrix. This also means that these dynamically generated states should be generated by means of a reasonable unitary scheme with the input of only the lowest order chiral Lagrangian, with a scale of regularization of the natural size, around 1 GeV. This was indeed the case, and it was found that the Bethe Salpeter equation with the lowest order chiral Lagrangian reproduced perfectly well the meson meson scattering in the scalar sector as well as the scalar resonances up to 1.2 GeV [19–22].

Turning back to the present subject of baryon resonances, one computes scattering transition amplitudes between all meson baryon channels, and one searches for poles for resonances in the second Riemann sheet. The poles provide the mass and width of the resonance states and, in addition, the
residues at the poles provide the product of the couplings of the resonance to the initial and final states of the considered transition scattering matrix element. In this method, it is not straightforward to evaluate other properties of the resonance, like magnetic moments, since, unlike ordinary quantum mechanical problems, in the present approach we do not have wave functions and operators manifestly. Therefore, we need to explore an alternative method to compute resonance magnetic moments from scattering matrices. This is the subject of the present work. We compute the magnetic moments of the \( \Lambda(1405) \) and \( \Lambda(1670) \) resonances, as well as the transition magnetic moment from the \( \Lambda(1670) \) to the \( \Lambda(1405) \), which allows us to determine the partial decay width for the decay \( \Lambda(1670) \to \Lambda(1405) \gamma \). We also compare the results obtained here with those of ordinary quark models showing that there are appreciable differences between them. This offers evidence that the nature of these states as dynamically generated from the multiple scattering of coupled channels of mesons and baryons differs from an ordinary quark model description.

The paper is organized as follows. In Sec. II, we briefly describe the model that we use and show in detail the method to compute scattering matrices. In Sec. III, we compare the scattering matrices with a resonance dominant form and extract the magnetic moments. In Sec. IV, we present our numerical results, which are compared with quark model results in Sec. V. The final section summarizes our findings.

II. EVALUATION OF THE MAGNETIC MOMENT

The procedure to evaluate the magnetic moment of the resonances proceeds in an analogous way to that for the \( N^*N^* \pi \) coupling in [7]. We evaluate the \( T \) matrix for the process \( MB \to M'B' \gamma \) using the chiral Lagrangian for the coupling of the mesons and baryons and for the photon to the mesons and baryons. We sum the Feynman diagrams which generate the resonance both on the left and on the right of the photon coupling. Isolation of resonance poles from these diagrams then allows us to evaluate the resonance magnetic moment.

The \( \Lambda(1405) \) resonance is generated in [4] by means of the Bethe-Salpeter equation with a cutoff to regularize the loop integrals. The Bethe-Salpeter equation is given by

\[
T = V + VGT, \tag{1}
\]

where in the present method the term \( VGT \) is given as a matrix product of the potential \( V \), the meson baryon propagator \( G \), and the \( T \) matrix. The diagonal matrix \( G \) contains the loop integral of a meson and baryon propagators. In general, the product \( VGT \) involves an integral over off-shell momenta. In the present approach that integral is greatly simplified, reducing the problem to a matrix product due to the on-shell factorizations of \( V \) and \( T \). The on-shell factorization in [4] was done by incorporating the off-shell part of the loops into renormalization of couplings of the lowest order Lagrangian, in analogy to what was done in the meson meson interaction in [19]. An explicit demonstration of the cancellation of these terms with tadpole corrections can also be seen in [23] for the \( p \)-wave meson meson interaction in the \( p \) channel. The on-shell factorization allows one to solve Eq. (1) to give

\[
T = [1 - VG]^{-1} V, \tag{2}
\]

in a simple matrix inversion. This has also been derived using the \( N/D \) unitarization method and dispersion relations in [5]. In this latter paper [5] the regularization of the loops is done by means of dimensional regularization with subtraction constants in the \( G \) function. The same method was used in [10] to obtain the \( \Lambda(1405) \) and \( \Lambda(1670) \) resonances, which is the one we follow here. The Feynman diagrams summed by Eqs. (1) and (2) are given in Fig. 1.

The \( s \)-wave meson baryon interaction potential \( V \) is derived from the second order terms in the meson field of the chiral Lagrangian [24,25]:

\[
V_{ij} = -C_{ij} \frac{1}{4f} (2 \sqrt{s} - M_i - M_j) \left( \frac{M_i + E}{2M_i} \right)^{1/2} \left( \frac{M_j + E}{2M_j} \right)^{1/2}, \tag{3}
\]

where the coefficients \( C_{ij} = C_{ji} \) are given in [4] and the meson decay constant \( f \) is taken as an average value \( f = 1.123 f_\pi \). The \( G \) function for each meson baryon channel is given by

\[
G_i(\sqrt{s}) = \frac{i 2M_i}{16\pi^2} \int \frac{d^4q}{(2\pi)^4} \left( P - q \right)^2 - M_i^2 + i \epsilon \left( q^2 - M_i^2 + i \epsilon \right)
\]

\[
= \frac{2M_i}{16\pi^2} \left[ a(\mu) + b(\mu) \ln \frac{M_i^2 - M^2 + s}{2s} \ln \frac{M_i^2 - M^2 + s}{2s} \right]
\]

\[
+ \frac{\bar{q}_i}{\sqrt{s}} \left( \ln[s -(M_i^2 - m_i^2) + 2\bar{q}_i \sqrt{s}] \right)
\]

\[
+ \ln[s + (M_i^2 - m_i^2) + 2\bar{q}_i \sqrt{s}] \right)
\]

\[
- \ln[-s -(M_i^2 - m_i^2) + 2\bar{q}_i \sqrt{s}] \right)
\]

\[
- \ln[-s -(M_i^2 - m_i^2) + 2\bar{q}_i \sqrt{s}] \right), \tag{4}
\]

where \( m \) and \( M \) are taken to be the observed meson and baryon masses, respectively, and \( \mu \) is a regularization scale which is chosen to be 630 MeV as in [10]. This value for the cutoff of the three-momentum of the intermediate states was obtained in [4] by fitting the data of \( K^-N \) scattering into different channels plus the properties of the \( \Lambda(1405) \) resonance. Actually, since this was the only free parameter of the theory, it was fitted to reproduce the position of that resonance and this was sufficient to reproduce its width plus the low energy cross sections of \( K^-p \) to its different coupled channels. In [10], since one is using dimensional regularization and subtraction constants, the choice of \( \mu \) is of course
FIG. 2. The elementary couplings of the photon to the components of the meson baryon amplitude. The wavy line denotes the photon.

arbitrary, but it was chosen to be the same as the cutoff in [4], as was also done in [5], to facilitate comparison of the works.

The subtraction constants \( a_I \) are of the order of \(-2\), which is a natural size as shown in [5]. The values chosen in [10], which reproduce the results of [4] calculated with just one cutoff, are

\[
\begin{align*}
  a_{\bar{K}N} &= -1.84, \quad a_{\pi\Sigma} = -2.00, \quad a_{\pi\Lambda} = -1.83, \\
  a_{\eta\Sigma} &= -2.25, \quad a_{\eta\Lambda} = -2.38, \quad a_{K\Xi} = -2.67.
\end{align*}
\]

Note that, as mentioned in [10], the use of physical masses in the former equations is introducing effectively some contributions of higher orders in the chiral counting. In the standard chiral approach one would be using the average mass of the octets in the chiral limit and higher order Lagrangians involving SU(3) breaking terms would generate the mass differences. By introducing the physical masses one guarantees that the phase space for the reactions, thresholds, and unitarity in coupled channels are respected from the beginning.

The elementary couplings of the photon to the components of the meson baryon amplitude at lowest order of the chiral expansion are shown in Fig. 2. Now, if we want to generate the resonance on the left and right sides of the photon coupling, we must consider the diagrams shown in Fig. 3. The diagrams of row (b) in Fig. 3 vanish, given the s-wave nature of the meson baryon vertices and the \( q \cdot q_L \) coupling of the photon to the mesons, which makes the integral over the loop variable \( q_L \) vanish. The remaining couplings are those of the photon to the baryons and the analogous ones with two extra meson lines. The spin dependent part of these couplings needed for the evaluation of magnetic moments is given by [26], where a chiral perturbative calculation of the baryon magnetic moments was done, continuing work initiated in [27], and read as

\[
\begin{align*}
  [S^\mu, S^\nu] F_{\mu\nu} &\rightarrow -i \hat{\epsilon} \times \hat{q} \cdot \hat{\epsilon} \\
\end{align*}
\]

FIG. 3. Diagrams for the coupling of the photon to the resonance dynamically generated in meson baryon scattering.

\[
\begin{align*}
  L &= -\frac{i}{4M_p} b_6^F \langle \bar{B} [S^\mu, S^\nu] F_{\mu\nu}, B \rangle \\
  &\quad - \frac{i}{4M_p} b_6^D \langle \bar{B} [S^\mu, S^\nu] F_{\mu\nu}, B \rangle, \\
\end{align*}
\]

with

\[
F_{\mu\nu}^+ = -e (u^\dagger Q F_{\mu\nu} + u Q F_{\mu\nu}^\dagger),
\]

\[
F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu.
\]

where \( M_p \) is the mass of proton, \( A_\mu \) is the electromagnetic field, and \( b_6^F \) and \( b_6^D \) are parameters to be fitted so as to reproduce the magnetic moments of the ground state baryons. In Eq. (6), \( \langle \cdots \cdots \rangle \) means the trace over flavor indices, \( B \) is the SU(3) matrix for the baryon field [24,25], and \( S^\mu \) are spin matrices as explained below. In Eq. (7), \( Q \) is the charge matrix for the \( u,d,s \) quarks: \( Q = \frac{1}{2} \text{diag}(2,-1,-1) \) and \( u^2 = U = \exp(i \sqrt{2} \Phi/f) \) where \( \Phi \) is the SU(3) matrix of the pseudoscalar meson field [24,25,28]. In the baryon rest frame the operator \( S^\mu \) becomes \( \hat{\sigma}/2 \) and, then

\[
\langle S^\mu, S^\nu \rangle \rightarrow -i \hat{\epsilon} \times \hat{q} \cdot \hat{\epsilon}
\]
in the Coulomb gauge \( \epsilon^0 = 0, \epsilon \cdot q = 0 \) and for an outgoing photon. Thus the vertex from the Lagrangian of Eq. (6) can be written as

\[
L \rightarrow -\frac{i}{2M_p} \epsilon \times q \left( \frac{1}{2} b_6^F \langle \bar{B} [(u^\dagger Q u + u Q u^\dagger), B] \rangle - \frac{1}{2} b_6^D \langle \bar{B} [(u^\dagger Q u + u Q u^\dagger), B] \rangle \right).
\]

By expanding \( u \) in terms of the meson field we obtain the expressions for both the \( \gamma BB^+ \) and \( \gamma BB^+ M M^\prime \) vertices. By taking \( u = 1 \) we obtain the magnetic moments of the ground state octet baryons,

\[
\mu_i = d_i b_6^D + f_i b_6^F,
\]

where the coefficients \( d_i \) and \( f_i \) are given in Table I. One immediately realizes that by setting \( b_6^D = 0 \) and \( b_6^F = 1 \) one obtains the ordinary magnetic moments of the baryons without anomalous contributions. Fitting the values of Eq. (12) to the observed magnetic moments of the baryons one obtains

\[
b_6^D = 2.40, \quad b_6^F = 1.82.
\]
TABLE II. $X_{ij}$ coefficient of Eq. (14). $X_{ij}=X_{ji}$.

very similar to those given in [26], and $b_6^D=2.39$, $b_6^F=1.77$, when including the unity in $b_6^F$ to account for the ordinary magnetic moment. One word of caution is called at this point. The values quoted here for these two parameters correspond to the fit to the magnetic moments at the tree level. If loops are taken into account then the fitted values of these two parameters are different [26]. The important thing to realize here is that the loops considered in the evaluation of the magnetic moments of the ground state baryons are vertex corrections in the $BB\gamma$ couplings, and, hence, are different than the loops of the meson baryon interaction considered here. We could have chosen the option of taking different values of the $b_6^D, b_6^F$ together with $BB\gamma$ vertex loop corrections. Yet what one wishes in our approach is to get a realistic value for the baryon magnetic moments in diagrams like the one in Fig. 2(c), and thus, the use of the tree level approximation, with the parameters fitted to the baryon magnetic moments at the tree level, is good enough for our purposes since it reproduces the magnetic moments of the ground state baryons quite fairly, with some discrepancies of at most 20%.

By expanding now $u$ up to two meson fields we obtain the vertices of diagram (a) of Fig. 2 with the result

$$-i\tilde{t}_{ij}^{(a)} = -\frac{\hbar}{2M_p} \left( \tilde{\sigma} \times \tilde{q} \right) \cdot \bar{\epsilon} \frac{1}{2f^2} [X_{ij} \cdot b_6^D + Y_{ij} \cdot b_6^F],$$  \hspace{1cm} (14)

where the coefficients $X_{ij}$ and $Y_{ij}$ are given in Tables II and III.

The evaluation of the amplitudes corresponding to the diagrams of Fig. 3 (the magnetic part) is straightforward. We obtain

$$-i\tilde{t}_{ij} = -\frac{e}{2M_p} \left( \tilde{\sigma} \times \tilde{q} \right) \cdot \bar{\epsilon} \frac{1}{2f^2} [X_{ij} \cdot b_6^D + Y_{ij} \cdot b_6^F],$$  \hspace{1cm} (15)

and

$$-i\tilde{t}_{ij} = \left\{ \sum_{lm} t_{ij} A_{lm} G_{lm} G_{lm}^{-1} + \sum_j t_{ij} \tilde{G}_{ij} \tilde{t}_{ij} \mu_B \right\}. \hspace{1cm} (16)$$

In this equation $t_{ij}$ is the scattering amplitude from the channel $i$ to $j$,

$$A_{lm} = \frac{1}{2f^2} [X_{lm} \cdot b_6^D + Y_{lm} \cdot b_6^F],$$  \hspace{1cm} (17)

and

$$\tilde{G}_{ij}(p) = i \int \frac{d^4k}{(2\pi)^4} D(k) G(p-k) G(p-k),$$  \hspace{1cm} (18)

with $D$ and $G$ the meson and baryon propagators. Here, by keeping up to linear terms in $\tilde{q}$, we have neglected the small momentum of the photon in the second baryon propagator. Therefore, we can write

$$\tilde{G}_{ij}(\sqrt{s}) = -\frac{\partial}{\partial \sqrt{s}} G_{ij}.$$  \hspace{1cm} (19)

This approximation allows us to obtain an analytic expression for $\tilde{G}_{ij}(\sqrt{s})$. In Eq. (16), we omit writing contributions from the $\Lambda - \Sigma^0$ transition magnetic moment. The contributions are negligible since the $\Lambda - \Sigma^0$ transition changes the
isospin; therefore, either the left or right resonances must have isospin 1, which is not the present case.

### III. COMPARISON TO THE RESONANCE DESCRIPTION

In order to extract a resonance magnetic moment from the scattering amplitude, Eq. (15) or (16), we assume that resonances are dynamically generated on the left and right of the photon coupling. First we parametrize the meson baryon scattering through the explicit resonance.

![Diagram](image1)

**FIG. 4.** (a) Diagrammatic representation of the photon coupling to an explicit resonance. (b) Diagrammatic representation of meson baryon scattering through the explicit resonance.

Dividing \( -i t'_{ij} \) by \( t_{ij} \) and by \( (e/2M_p)(\bar{s} \times \bar{q}) \cdot \bar{e} \) we cancel the coupling constants and one propagator. Thus by evaluating this ratio at the \( \Lambda^+ \) pole, where the amplitudes are dominated by the resonance, and recalling Eq. (15), we have

\[
\mu_{\Lambda^+} = \lim_{z \to z_R} \frac{-i t'_{ij}(z)}{t_{ij}(z)} = \text{Res}_{z \to z_R} \left( \frac{-i t'_{ij}(z)}{t_{ij}(z)} \right)
\]

where \( z_R \) denotes the position of the pole in the second Riemann sheet, \( z_R = M_R + i\Gamma/2 \). In fact, there exist two poles around the region of the \( \Lambda(1405) \) [5], located at \( z_R = 1426 + 16i \) and \( 1390 + 66i \) MeV. The former pole largely couples to the \( K\bar{N} \) state, whereas the latter one couples predominantly to the \( \pi\Sigma \) state. Both poles may contribute to the resonance \( \Lambda(1405) \). We evaluate the magnetic moment at both poles. For the \( \Lambda(1670) \) the pole position is \( z_R = 1680 + 20i \) MeV.

Similarly, we can also evaluate the transition amplitude between the \( \Lambda(1670) \) and \( \Lambda(1405) \) resonances. This is accomplished by putting different energies \( \sqrt{s_1} \) and \( \sqrt{s_2} \) on the transition amplitudes \( t_{ij} \) appearing on the left and right of the photon coupling in Eq. (16). Then by taking \( \sqrt{s_1} = z_1R \) for the first resonance \( [\Lambda(1670)] \) and \( \sqrt{s_2} = z_2R \) for the second resonance \( [\Lambda(1405)] \), we would find

\[
\mu_{\Lambda(1670)\to\Lambda(1405)} = \lim_{z \to z_1R} \frac{-i t'_{ij}(z_1, z_2) g_1(1670) g^*(1405)}{t_{ij}(z_1) t_{jj}(z_2)}
\]

The analysis in the complex plane has the advantage of making the background contributions negligible since the
evaluations are done exactly at the poles of the resonances. The magnetic moment evaluated in the complex plane, however, has a complex value, which might induce uncertainties since one is extrapolating from the real axis to the complex plane. Hence, to avoid these uncertainties, we also calculate the amplitudes on the real axis in the first Riemann sheet. The magnetic moments are then defined by

$$\mu_{\Lambda} = -\frac{i}{\sqrt{s}} \left[ \frac{\partial}{\partial \sqrt{s}} f_{ij}(\sqrt{s}) \right],$$

where both the coupling constants and the resonance propagators cancel to provide the magnetic moment of the resonance. In order to eliminate background we choose external gators cancel to provide the magnetic moment of the resonance. We show in Fig. 8 the numerator and the denominator of Eq. (24)

$$\mu_{\Lambda} = \frac{[ -i \hat{t}_{K} \gamma_{K}(\sqrt{s_{1}}, \sqrt{s_{2}}) ] \left[ f_{ij}(\sqrt{s_{1}}) \right]}{[ -i \hat{t}_{\Sigma} \gamma_{\Sigma}(\sqrt{s_{1}}) ] \left[ f_{ij}(\sqrt{s_{2}}) \right]}$$

and we proceed as before to evaluate the ratio and the uncertainties. We show in Fig. 8 the numerator and the denominator of Eq. (25) for fixed $\sqrt{s_{1}} = 1681$ MeV as a function of $\sqrt{s_{2}}$ in the left panels and for fixed $\sqrt{s_{1}} = 1423$ MeV as a function of $\sqrt{s_{2}}$ in the right panels.

Experimentally, magnetic moments of resonances may be extracted from bremsstrahlung processes, which are carefully compared with theoretical models. On the other hand, the transition magnetic moment between $\Lambda(1670)$ and $\Lambda(1405)$ could be directly investigated from the decay $\Lambda(1670) \rightarrow \Lambda(1405) \gamma$. The width for this transition is given by

$$\Gamma = \frac{1}{\pi} \frac{M_{\Lambda(1405)}}{M_{\Lambda(1670)}} q^{2} \left( \frac{e^2 \mu_{\Lambda(1670) \rightarrow \Lambda(1405)}}{2M_{\rho}} \right)^{2},$$

where $q$ is the photon momentum in the $\Lambda(1670)$ rest frame.

**IV. RESULTS**

Comparison of the numerator and denominator in Eq. (24) for the $\Lambda(1405)$ with the $\bar{K}N \rightarrow \gamma \bar{K}N$ and $\bar{K}N \rightarrow \gamma \pi \Sigma$ channel and performing the ratios discussed in the former section we obtain a value

$$\mu_{\Lambda(1405)} = + (0.24 - 0.45)$$

in units of the nuclear magneton $\mu_{N} = e/2M_{\rho}$. The large uncertainty in the result obtained comes from the energy range where the amplitudes of the ratio of Eq. (24) are evaluated. As seen in Figs. 5 and 6 the value of this energy, which signals the position of the resonance in the real axis, lies in the range 1418–1422 MeV for the $\bar{K}N$ channel and in the range 1403–1416 MeV for the $\pi \Sigma$ channel. The evaluation in the $\bar{K}N$ channel gives $\mu_{\Lambda(1405)} = + 0.44 \pm 0.06$, while the
$\bar{K}N \rightarrow \gamma \pi \Sigma$ channel produces a value 0.26 ± 0.07. We also evaluate the magnetic moment using the ratio of Eq. (22) at the pole in the second Riemann sheet, which gives a complex number with the module 0.41 ± 0.01 for the case of $z_R = 1426 + 16i$ and 0.30 ± 0.01 for $z_R = 1390 + 66i$. All possible isospin $I=0$ combinations $\bar{K}N$, $\pi \Sigma$, $\eta \Lambda$, and $K \Xi$ provide approximately the same value (the channel dependence is shown in the small error bar of the presented value). This channel insensitivity in the evaluation in the complex plane implies that the ratio of Eq. (22) at the pole is dominated by the resonance and is not affected by background contaminations. It is interesting to note that the values in the complex plane are comparable with the value of Eq. (27). In addition, recalling that the pole at $z_R = 1426 + 16i$ couples largely to $\bar{K}N$ and that at $z_R = 1390 + 66i$ to $\pi \Sigma$, the channel (or energy) dependence of the magnetic moment evaluated on the real axis stems from a different contribution of each pole to the values of the amplitudes in the real axis.

For the case of the $\Lambda(1670)$ the ratio obtained from Fig. 7 with the $K \Xi$ channel gives us

$$\mu_{\Lambda(1670)} = -0.29 \pm 0.01, \quad (28)$$

with small uncertainty, and we find that the ratio of Eq. (24) is stable around the resonance region. It is also interesting to note that the analysis in the complex plane in the pole in the second Riemann sheet [Eq. (22)] gives in this case a value for the modulus of 0.23, which is similar to that of Eq. (28).

As in the preceding case, the analysis in the real plane allows us to obtain a real magnetic moment with a given sign.

For the case of the $\Lambda(1670)$ resonance region in units of $m^2$.

FIG. 6. Real and imaginary parts of (a) the numerator $-i \tilde{T}_{\bar{K}N \rightarrow \gamma \pi \Sigma}$ in Eq. (24) and (b) the denominator $-\partial \tilde{T}_{\bar{K}N \rightarrow \pi \Sigma} / \partial \sqrt{s}$ in Eq. (24) around the $\Lambda(1405)$ resonance region in units of $m^2$.

FIG. 7. Real and imaginary parts of (a) the numerator $-i \tilde{T}_{K \Xi \rightarrow \gamma K \Xi}$ in Eq. (24) and (b) the denominator $-\partial \tilde{T}_{K \Xi \rightarrow K \Xi} / \partial \sqrt{s}$ in Eq. (24) around the $\Lambda(1670)$ resonance region in units of $m^2$.

FIG. 8. Real and imaginary parts of the numerator (a),(c) and the denominator (b),(d) in Eq. (25) in units of $m^4$. In (a) and (b), $\sqrt{s}_1$ is fixed at 1680 MeV and the numerator and the denominator are functions of $\sqrt{s}_2$. In (c) and (d), $\sqrt{s}_2$ is fixed at 1640 MeV and the numerator and the denominator are functions of $\sqrt{s}_1$. 

025203-7
Here we have employed standard notations

\[ \vec{\rho} = \frac{1}{\sqrt{2}}(\vec{x}_2 - \vec{x}_1), \quad \vec{\lambda} = \frac{1}{\sqrt{6}}(\vec{x}_2 + \vec{x}_1 - 2\vec{x}_3), \]

\[ \psi(\vec{x}) : \text{ } p\text{-wave orbital wave functions,} \]

\[ \chi_{\rho,\lambda,S} : \text{ flavor wave functions of } \rho, \lambda, \text{ and } S \text{ symmetry.} \]

\[ \phi_{\rho,\lambda,A} : \text{ flavor wave functions of } \rho, \lambda, \text{ and } A \text{ symmetry.} \]

Furthermore, in Eq. (31), orbital and spin wave functions are coupled to the total spin jm.

In the nonrelativistic description, the magnetic moment operator is given by the sum of twice spin and orbital angular momentum:

\[ \vec{\mu} = \sum_{i=1}^{3} [\mu^\sigma(i)\vec{\sigma}(i) + \mu^l(i)\vec{l}(i)]. \]

Here \( \mu^\sigma(i) \) and \( \mu^l(i) \) are spin and orbital magnetons of the \( i \)th quark. If constituent quarks are considered to be simple Dirac particles, they are \( \mu^\sigma(i) = \mu^l(i) = \mu_u, \mu_d, \text{ and } \mu_s \) for \( u, d, \text{ and } s \) quarks, where

\[ \mu_u = \frac{2}{3} \frac{1}{2m_u}, \]

\[ \mu_d = -\frac{1}{3} \frac{1}{2m_d}, \]

\[ \mu_s = -\frac{1}{3} \frac{1}{2m_s}. \]

In actual computations, it is sufficient to give matrix elements of \( \mu_3 \) in the basis of \( |1\rangle = |2\rangle = |8\rangle, \) and \( |3\rangle = |16\rangle \). It is straightforward to obtain

\[ \sum_{i=1}^{3} \mu^\sigma(i)\sigma_3(i) = \frac{1}{9} \begin{pmatrix} -A & 2B & B \\ 2B & 5A & 2B \\ B & 2B & -A \end{pmatrix}, \]
where $A = \mu_u + \mu_d + \mu_s$ and $B = \mu_u + \mu_d - 2 \mu_s$. From a group theoretical point of view of flavor SU(3), it is shown that nine components of magnetic moments are expressed in terms of four independent quantities. Here two of them become irrelevant due to the SU(6) construction of the quark model wave function.

By writing a $\Lambda$ state as

$$|\Lambda\rangle = a_1|1\rangle + a_2|2\rangle + a_3|3\rangle,$$  \hspace{1cm} (34)

where the coefficients must satisfy the normalization condition $a_1^2 + a_2^2 + a_3^2 = 1$, we find the corresponding matrix element

$$\langle \Lambda |\mu_3|\Lambda\rangle = \sum_{nm} a_n a_m \langle n|\mu_3|m\rangle.$$  \hspace{1cm} (35)

The coefficients are determined by assuming suitable interactions between quarks. Here we employ two parameter sets, Isgur-Karl (IK) [1] and Hey-Litchfield-Cashmore (HLC) [30], the values of which are shown in Table V. We summarize the results for the magnetic moments in Table VI, where the transition magnetic moment is also shown. We used quark masses $m_u = 338\ MeV$, $m_d = 322\ MeV$, and $m_s = 510\ MeV$ as taken from the Review of Particle Physics [32]. We find that the magnetic moments of the $\Lambda(1405)$ and $\Lambda(1670)$ states, as well as the transition magnetic moment, are sensitive to the coefficients of the wave functions. The diagonal moments are small and change within ±0.3. If physical states are supplemented by another state [say, $\Lambda(1800)$], then the sum of the three diagonal magnetic moments is invariant and is equal to the trace of the matrix $\mu_3$ (sum rule). If there is no mixing between $|1\rangle$, $|2\rangle$, and $|3\rangle$

and $\Lambda(1405)$ and $\Lambda(1670)$ are regarded as pure singlet ($|3\rangle$) and octet ($|1\rangle$), respectively, their magnetic moments vanish in the SU(3) symmetric limit, $m_u = m_d = m_s$, since they are proportional to the factor $A$. This explains the relatively small and unstable values of the diagonal matrix elements.

In contrast, the off-diagonal magnetic moment takes a relatively large value. Typically, it is $\mu(\Lambda(1670) \rightarrow \Lambda(1405)) \sim 0.5$, which is more than one order of magnitude larger than the values of the chiral unitary approach. In the SU(3) symmetric limit, the off-diagonal matrix element survives as it is proportional to the factor $B$.

**VI. CONCLUSION**

We have introduced here the formalism to evaluate magnetic moments and the transition magnetic moment of the two $\Lambda^*$ resonances, $\Lambda(1405)$ and $\Lambda(1670)$, which are dynamically generated within U$_{\chi}$PT. At the same time we have done the numerical evaluations and have determined the actual value for these magnitudes. The values obtained are $\mu_{\Lambda(1405)} = (0.2 - 0.5)\mu_N$, smaller than that of the $\Delta(\sim -0.6\mu_N)$ and of opposite sign. For the $\Lambda(1670)$ we obtain $\mu_{\Lambda(1670)} \sim -0.29\mu_N$, also smaller than that of the $\Lambda$ and with the same sign, while for the transition magnetic moment we obtain a value $|\mu_{\Lambda(1670) \rightarrow \Lambda(1405)}| \sim 0.023\mu_N$, which leads to a branching ratio of the $\Lambda(1670)$ to $\Lambda(1405)$ $\gamma$ channel of the order of $2 \times 10^{-6}$. The results of the U$_{\chi}$PT method are different from those obtained with the quark models, reflecting the different nature attributed to the resonances in those models. One of the interesting results obtained in this work is the abnormally small decay width for the $\Lambda(1670) \rightarrow \Lambda(1405)$ $\gamma$ transition, which differs in two orders of magnitude from the quark model predictions. Short of a measurement of the transition, which could be difficult given the small numbers predicted, even the determination of an upper bound would provide interesting information about the nature of these resonances.

From the theoretical point of view it would be interesting to see results obtained for the magnitudes evaluated here by using chiral quark models [33–36], which, although not unitarized, would somehow incorporate elements of the meson baryon cloud present in the dynamically generated resonances. Also, advances in the line of putting together elements of quark models together with unitarity [37] would be most welcome.
