Previously, using artificial cell systems, we identified receptor heteromers between the dopamine D<sub>1</sub> or D<sub>2</sub> receptors and the histamine H<sub>3</sub> receptor. In addition, we demonstrated two biochemical characteristics of the dopamine D<sub>1</sub> receptor-histamine H<sub>3</sub> receptor heteromer. We have now extended this work to show the dopamine D<sub>1</sub> receptor-histamine H<sub>3</sub> receptor heteromer exists in the brain and serves to provide a novel link between the MAPK pathway and the GABAergic neurons in the direct striatal efferent pathway. Using the biochemical characteristics identified previously, we found that the ability of H<sub>3</sub> receptor activation to stimulate p44 and p42 extracellular signal-regulated MAPK (ERK 1/2) phosphorylation was only observed in striatal slices of mice expressing D<sub>1</sub> receptors but not in D<sub>1</sub> receptor-deficient mice. On the other hand, the ability of both D<sub>1</sub> and H<sub>3</sub> receptor antagonists to block MAPK activation induced by either D<sub>1</sub> or H<sub>3</sub> receptor agonists was also found in striatal slices. Taken together, these data indicate the occurrence of D<sub>1</sub>-H<sub>3</sub> receptor complexes in the striatum and, more importantly, that H<sub>3</sub> receptor agonist-induced ERK 1/2 phosphorylation in striatal slices is mediated by D<sub>1</sub>-H<sub>3</sub> receptor heteromers. Moreover, H<sub>3</sub> receptor-mediated phospho-ERK 1/2 labeling co-distributed with D<sub>1</sub> receptor-containing but not with D<sub>2</sub> receptor-containing striatal neurons. These results indicate that D<sub>1</sub>-H<sub>3</sub> receptor heteromers work as processors integrating dopamine- and histamine-related signals

involved in controlling the function of striatal neurons of the direct striatal pathway.

The striatum is the main input structure of the basal ganglia, which are subcortical structures involved in the processing of information related to the performance and learning of complex motor acts. It is widely accepted that dopamine receptor subtypes, which are fundamental for motor control and are implicated in numerous neuropsychiatric disorders, are largely segregated in the two subtypes of medium spiny neurons (MSNs),<sup>4</sup> the most populated neuronal type in the striatum. Dopamine D<sub>2</sub> receptors (D<sub>2</sub>Rs) are mostly localized in the striatopallidal MSNs, which express the peptide enkephalin and which gives rise to the indirect striatal efferent pathway, whereas dopamine D<sub>1</sub> receptors (D<sub>1</sub>Rs) are mostly expressed by the striatonigral MSNs, which express substance P and dynorphin and constitute the direct striatal efferent pathway (1, 2). Dopaminergic drugs activate the ERK transduction pathway, which is involved in basic physiological processes and in synaptic plasticity (3). In the dopamine-depleted striatum, ERK signaling is implicated in the development of L-DOPA-induced dyskinesia. Thus, in dopamine-denervated mice, L-DOPA activates ERK signaling specifically in D<sub>1</sub>Rs containing striatonigral MSNs but not in D<sub>2</sub>Rs containing striatopallidal MSNs (4). This regulation may result in ERK-dependent changes in striatal plasticity leading to dyskinesia.

Histamine is an important regulatory transmitter in the nervous system involved in the sleep/wake cycle, attention, memory, and other functions. Four histamine receptor types (H<sub>1</sub>R–H<sub>4</sub>R) have been cloned. H<sub>3</sub>Rs are expressed in abundance in the brain and high densities are particularly found in the striatum (5–7). H<sub>3</sub>Rs were first identified as autoreceptors (8), but they were later found to act as heteroreceptors (9).

<sup>4</sup> The abbreviations used are: MSN, medium spiny neurons; D<sub>2</sub>R, dopamine D<sub>2</sub> receptor; H<sub>1</sub>R, histamine H<sub>1</sub> receptor; D<sub>1</sub>R, dopamine D<sub>1</sub> receptor; RAMH, R(-)- $\alpha$ -methylhistamine dihydrochloride.

The major localization of striatal H<sub>3</sub>Rs is postsynaptic (5, 10), and most probably in both subtypes of MSNs (6, 10). Histamine, by means of interactions with striatal H<sub>3</sub>Rs, plays an important role in the modulation of dopamine neurotransmission (11–14). At the behavioral level, it was shown that stimulation of postsynaptic H<sub>3</sub>R counteracts the motor activation induced by D<sub>1</sub>R and D<sub>2</sub>R agonists in reserpinized mice (14). These interactions may be related to the ability of H<sub>3</sub>Rs to form heteromers with dopamine receptors. In fact, D<sub>1</sub>R-H<sub>3</sub>R and D<sub>2</sub>R-H<sub>3</sub>R heteromerization was demonstrated by biophysical techniques in mammalian cells (14, 15). However, their presence in the brain remained to be demonstrated. In addition, if H<sub>3</sub>Rs form heteromers with both D<sub>1</sub>R and D<sub>2</sub>R, is there a functional difference between these two receptor heteromer pairs? One might expect that because the D<sub>1</sub>R and D<sub>2</sub>R receptors are found in two different neuronal pathways that the different heteromers might confer different properties. Here, we have explored this idea by taking advantage of unique properties of the D<sub>1</sub>R-H<sub>3</sub>R heteromers to provide evidence for their presence in rodent brain. Previously, using an *in vitro* cell system, we found an important feature of the D<sub>1</sub>R-H<sub>3</sub>R heteromer is that H<sub>3</sub>R agonists only activate ERK 1/2 in a receptor heteromer context, but not in cells expressing H<sub>3</sub>Rs without D<sub>1</sub>R (15). Here, by taking advantage of this distinct ERK 1/2 signaling characteristic, we demonstrate the occurrence of D<sub>1</sub>R-H<sub>3</sub>R heteromers in rodent striatum. Despite H<sub>3</sub>Rs being expressed in both D<sub>1</sub>R and D<sub>2</sub>R containing neurons, histamine-receptor-mediated phosphorylation of the ERK 1/2 kinase occurred only in neurons expressing D<sub>1</sub>R and not in those with D<sub>2</sub>R. Thus, D<sub>1</sub>-H<sub>3</sub> receptor heteromers confer a direct link to MAPK activation within the GABAergic neurons of the direct striatal efferent pathway.

## EXPERIMENTAL PROCEDURES

**Animals**—Sprague-Dawley male rats, 7–9 weeks old and weighing 200–250 g, were provided by the Animal Service of the Universidad Autónoma de Barcelona (Barcelona, Spain). Six-to-eight-month-old wild-type littermates and dopamine D<sub>1</sub> receptor knock-out C57BL6 male mice, weighing 25–30 g, were provided by Instituto Cajal (Consejo Superior de Investigaciones Científicas; Madrid, Spain) and generated by homologous recombination as described previously (16). Rats (2 per cage) or mice (five per cage) were housed in a temperature (21 ± 1 °C) and humidity-controlled (55 ± 10%) room with a 12:12 h light/dark cycle (light between 08:00 and 20:00 h) with food and water *ad libitum*. Animal procedures were conducted according to standard ethical guidelines (European Communities Council Directive 86/609/EEC) and approved by the local (Universidad Autónoma de Barcelona or Consejo Superior de Investigaciones Científicas) ethical committee.

**Cell Culture and Membrane Preparation**—SK-N-MC/H<sub>3</sub> cells were grown in Eagle's minimal essential medium, supplemented with 10% FBS, 50 units/ml penicillin, 50 μg/ml streptomycin, nonessential amino acids, 2 mmol/liter L-glutamine, and 50 μg/ml sodium pyruvate at 37 °C in a humidified atmosphere of 5% CO<sub>2</sub> to 80% confluence. The SK-N-MC cells stably expressing the human H<sub>3</sub>R (SK-N-MC/H<sub>3</sub>) were provided by Johnson & Johnson Pharmaceutical Research & De-

velopment, L.L.C. Cells were disrupted with a Polytron homogenizer (PTA 20 TS rotor, setting 3; Kinematica, Basel, Switzerland) in 50 mM Tris-HCl buffer, pH 7.4, containing a protease inhibitor mixture (1/1000; Sigma). The cellular debris was removed by centrifugation at 13,000 × g for 5 min at 4 °C, and membranes were obtained by centrifugation at 105,000 × g for 1 h at 4 °C. Membranes were lysed in 50 mM Tris-HCl, pH 7.4, containing 50 mM NaF, 150 mM NaCl, 45 mM β-glycerophosphate, 1% Triton X-100, 20 μM phenylarsine oxide, 0.4 mM NaVO<sub>4</sub>, and protease inhibitor mixture to be processed by Western blot.

**Brain Slice Preparation**—Rats and mice were decapitated with a guillotine, and the brains were rapidly removed and placed in ice-cold oxygenated (O<sub>2</sub>/CO<sub>2</sub>: 95/5%) Krebs-HCO<sub>3</sub><sup>-</sup> buffer (124 mM NaCl, 4 mM KCl, 1.25 mM NaH<sub>2</sub>PO<sub>4</sub>, 1.5 mM MgCl<sub>2</sub>, 1.5 mM CaCl<sub>2</sub>, 10 mM glucose, and 26 mM NaHCO<sub>3</sub>, pH 7.4). The brains were sliced at 4 °C in a brain matrix (Zivic Instruments, Pittsburgh, PA) into 0.5-mm coronal slices. Slices were kept at 4 °C in Krebs-HCO<sub>3</sub><sup>-</sup> buffer during the dissection of the striatum. Each slice was transferred into an incubation tube containing 1 ml of ice-cold Krebs-HCO<sub>3</sub><sup>-</sup> buffer. The temperature was raised to 23 °C and after 30 min, the medium was replaced by 2 ml Krebs-HCO<sub>3</sub><sup>-</sup> buffer (23 °C). The slices were incubated under constant oxygenation (O<sub>2</sub>/CO<sub>2</sub>: 95/5%) at 30 °C for 4–5 h in an Eppendorf Thermomixer (5 Prime, Inc., Boulder, CO). The media was replaced by 200 μl of fresh Krebs-HCO<sub>3</sub><sup>-</sup> buffer and incubated for 30 min before the addition of ligands.

**ERK Phosphorylation Assays**—Striatal slices were incubated in the presence of the indicated concentrations of histamine H<sub>3</sub> or dopamine D<sub>1</sub> receptor ligands, prepared in Krebs-HCO<sub>3</sub><sup>-</sup> buffer. After the indicated incubation period, the solution was discarded, and slices were frozen on dry ice and stored at –80 °C. Slices were lysed by the addition of 500 μl of ice-cold lysis buffer (50 mM Tris-HCl pH 7.4, 50 mM NaF, 150 mM NaCl, 45 mM β-glycerophosphate, 1% Triton X-100, 20 μM phenylarsine oxide, 0.4 mM NaVO<sub>4</sub>, and protease inhibitor mixture). Cellular debris was removed by centrifugation at 13,000 × g for 5 min at 4 °C, and protein was quantified by the bicinchoninic acid method using bovine serum albumin dilutions as standard. To determine the level of ERK1/2 phosphorylation, equivalent amounts of protein (10 μg) were separated by electrophoresis on a denaturing 10% SDS-polyacrylamide gel and transferred onto PVDF-FL membranes. Odyssey blocking buffer (LI-COR Biosciences, Lincoln, Nebraska) was then added, and membranes were rocked for 90 min. Membranes were then probed with a mixture of a mouse antiphospho-ERK 1/2 antibody (1:2500, Sigma) and rabbit anti-ERK 1/2 antibody (1:40,000, Sigma) for 2–3 h. The 42 and 44 kDa bands corresponding to ERK 1 and ERK 2 were visualized by the addition of a mixture of IRDye 800 (anti-mouse) antibody (1:10,000, Sigma) and IRDye 680 (anti-rabbit) antibody (1:10,000, Sigma) for 1 h and scanned by the Odyssey infrared scanner (LI-COR Biosciences). Bands densities were quantified using the scanner software and exported to Microsoft Excel. The level of phosphorylated ERK 1 and phosphorylated ERK 2 was normalized for differences in loading using the total ERK 1/2 protein band intensities.

## Dopamine D<sub>1</sub>-histamine H<sub>3</sub> Receptor Heteromers in Striatum

**Immunohistochemistry**—Striatal slices were incubated with the indicated H<sub>3</sub>R ligands in Krebs-HCO<sub>3</sub><sup>-</sup> buffer for 10 min and fixed with 4% paraformaldehyde solution (Antigenfix, DiaPath) for 1 h at room temperature with gentle agitation. The slices were then washed in TBS (50 mM Tris-HCl, 0.9% NaCl, pH 7.8), treated 5 min with 1% Na<sub>2</sub>BH<sub>4</sub> dissolved in TBS, followed by successive TBS washes until all Na<sub>2</sub>BH<sub>4</sub> was eliminated. Finally, the slices were cryopreserved in a 30% sucrose solution overnight at 4 °C and stored at -20 °C until sectioning. 15- $\mu$ m-thick coronal sections were cut on a freezing cryostat (Leica Jung CM-3000) and mounted on slide glass (three control and three treated coronal sections in each slide; STAR FROST PLUS, DELTALAB). Coronal sections were thawed at 4 °C, washed in TBS, and rocked in 7% normal donkey serum (SND, Sigma) in TBS for 1 h at 37 °C in a humidified atmosphere. Coronal sections were then incubated overnight at 4 °C in a humidified atmosphere with the primary antibodies: rabbit antiphospho-Thr<sup>202</sup>/Tyr<sup>204</sup> ERK 1/2 antibody (1:300, Cell Signaling Technology, Danvers, MA), guinea pig anti-D<sub>1</sub> antibody (1:100, Frontier Institute, Ishikari, Hokkaido, Japan) or guinea pig anti-D<sub>2</sub> antibody (1:100, Frontier Institute, Ishikari, Hokkaido, Japan) alone or in combination in a solution with 0.1% TBS-Tween, 0.1% BSA-acetylated (Aurion), 7% SND (250  $\mu$ l per slide). The specificity of these dopamine receptor antibodies has been previously shown by preabsorption tests with the antigen peptides and by mutually exclusive pattern and triple labeling in immunohistochemistry (17) and by Western blot (see “Results”). Coronal sections were washed in 0.05% TBS-T and left for 2 h at room temperature in a humidified atmosphere with the corresponding secondary antibodies: chicken anti-rabbit (1:200, Alexa Fluor 594, Invitrogen) and goat anti-guinea pig (1:200, Alexa Fluor 488, Invitrogen) in a solution with TBS-Tween 0.1%, BSA acetylated 0.1%, SND 7%, and then washed in TBS-T 0.05%, followed by a single wash in TBS before mounting in Mowiol medium (Calbiochem), covered with a glass, and left to dry at 4 °C for 24 h. Single and double immunostained slices were observed and imaged in a Leica SP2 confocal microscope (Leica Microsystems, Mannheim, Germany). Images were opened and processed with ImageJ confocal microscopy program and a Adobe Photoshop program (version 5.5; Seattle, WA). Double-labeled cells (cells stained for phospho-ERK 1/2 and D<sub>1</sub> or D<sub>2</sub> receptors) were counted in a total of two to three nonoverlapping fields of 45 coronal sections from 4 to 5 slices treated with medium (control), 1  $\mu$ M RAMH, or 1  $\mu$ M imetit.

Coronal sections from nontreated slices (six control coronal sections in each slide) were used for double-immunohistochemistry using rabbit anti-H<sub>3</sub>R antibody (1:200, Chemicon, Billerica, MA) and guinea pig anti-D<sub>1</sub>R antibody or guinea pig anti-D<sub>2</sub>R antibody as primary antibodies and goat anti-rabbit-peroxidase (1:200, Thermo Scientific, Fremont, CA) and goat anti-guinea pig (1:200, Alexa Fluor 488, Invitrogen) as secondary antibodies by the same procedure as described above. In this case, the amplification system for the red fluorophore, TSA-cyanine 3 (1:100, Tyramide Signal Amplification, PerkinElmer Life Science) was used as described in the TSA Plus fluorescence amplification kit, before mounting in

Mowiol medium. Double-labeled cells (cells stained for H<sub>3</sub> and D<sub>1</sub> or D<sub>2</sub> receptors) were counted in a total of two to three nonoverlapping fields of 15 coronal sections from four to five slices. In all cases, we did not observe staining in the absence of the primary antibodies.

**Coimmunoprecipitation**—The rat striatal tissue was disrupted with a Polytron homogenizer in 50 mM Tris-HCl buffer, pH 7.4, containing a protease inhibitor mixture (1/1000, Sigma). The cellular debris was removed by centrifugation at 13,000  $\times$  g for 5 min at 4 °C, and membranes were obtained by centrifugation at 105,000  $\times$  g for 1 h at 4 °C. Membranes were washed two more times at the same conditions and were solubilized by homogenization in ice-cold immunoprecipitation buffer (phosphate-buffered saline, pH 7.4, containing 1% (v/v) Nonidet P-40) and incubated for 30 min on ice before centrifugation at 105,000  $\times$  g for 1 h at 4 °C. The supernatant (1 mg/ml of protein) was processed for immunoprecipitation as described in immunoprecipitation protocol using a Dynabeads® Protein G kit (Invitrogen). Protein was quantified by the bicinchoninic acid method (Pierce) using bovine serum albumin dilutions as standard. Immunoprecipitates were carried out with rat anti-D<sub>1</sub> receptor antibody (1:1000, Sigma) or rabbit anti-D<sub>2</sub> receptor antibody (1:1000, Millipore, Billerica, MA) As negative control anti-calnexin antibody was used (1:1000, BD Biosciences Pharmingen). Immunoprecipitates were separated on a denaturing 10% SDS-polyacrylamide gel and transferred onto PVDF membranes. Membranes were probed with the primary antibodies guinea pig anti-D<sub>1</sub> antibody (1:1000, Frontier Institute, Ishikari, Hokkaido, Japan), guinea pig anti-D<sub>2</sub> antibody (1:1000, Frontier Institute) or goat anti-H<sub>3</sub>R antibody (1:500, Santa Cruz Biotechnology, Santa Cruz, CA) and the secondary antibodies goat anti-guinea pig-peroxidase (1:20,000, Sigma) and donkey anti-goat-peroxidase (1:20,000, Jackson ImmunoResearch Laboratories, West Grove, PA). Bands were visualized with a LAS-3000 (Fujifilm). Analysis of detected bands was performed by Image Gauge software (version 4.0) and Multi Gauge software (version 3.0).

## RESULTS

**D<sub>1</sub>R and H<sub>3</sub>R Are Functionally Coupled to MAPK Signaling Pathway in Brain Striatal Slices**—To establish whether D<sub>1</sub>R and H<sub>3</sub>R are functionally coupled to the MAPK pathway in rat striatum, slices were treated with a D<sub>1</sub>R or an H<sub>3</sub>R agonist, and ERK 1/2 phosphorylation was assayed as described under “Experimental Procedures.” The time response curve obtained after treatment with 10  $\mu$ M SKF 38393 (D<sub>1</sub>R agonist) or 0.1  $\mu$ M imetit (H<sub>3</sub>R agonist) showed that phosphorylation peaked at 10 min (Fig. 1*a*). Therefore, all subsequent assays were analyzed at 10 min of drug treatment. Dose-response curves for different D<sub>1</sub>R or H<sub>3</sub>R agonists are displayed in Fig. 1*b*. Both SKF 81297 and SKF 38393 (full and partial D<sub>1</sub>R agonists, respectively) were able to increase ERK 1/2 phosphorylation; SKF 81297 was more potent than SKF 38393. RAMH and imetit (H<sub>3</sub>R agonists) also increased ERK 1/2 phosphorylation, with imetit being more potent than RAMH. The results show that striatal slices contain D<sub>1</sub>R and H<sub>3</sub>R functionally coupled to MAPK signaling.

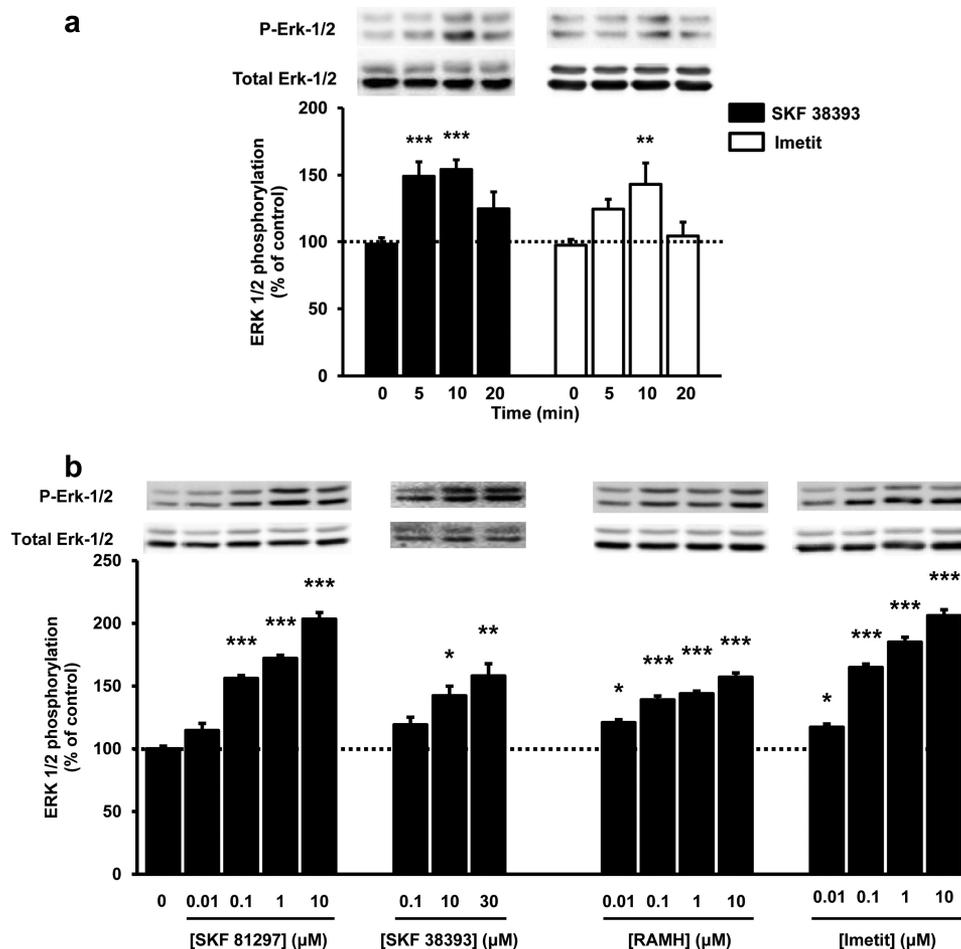

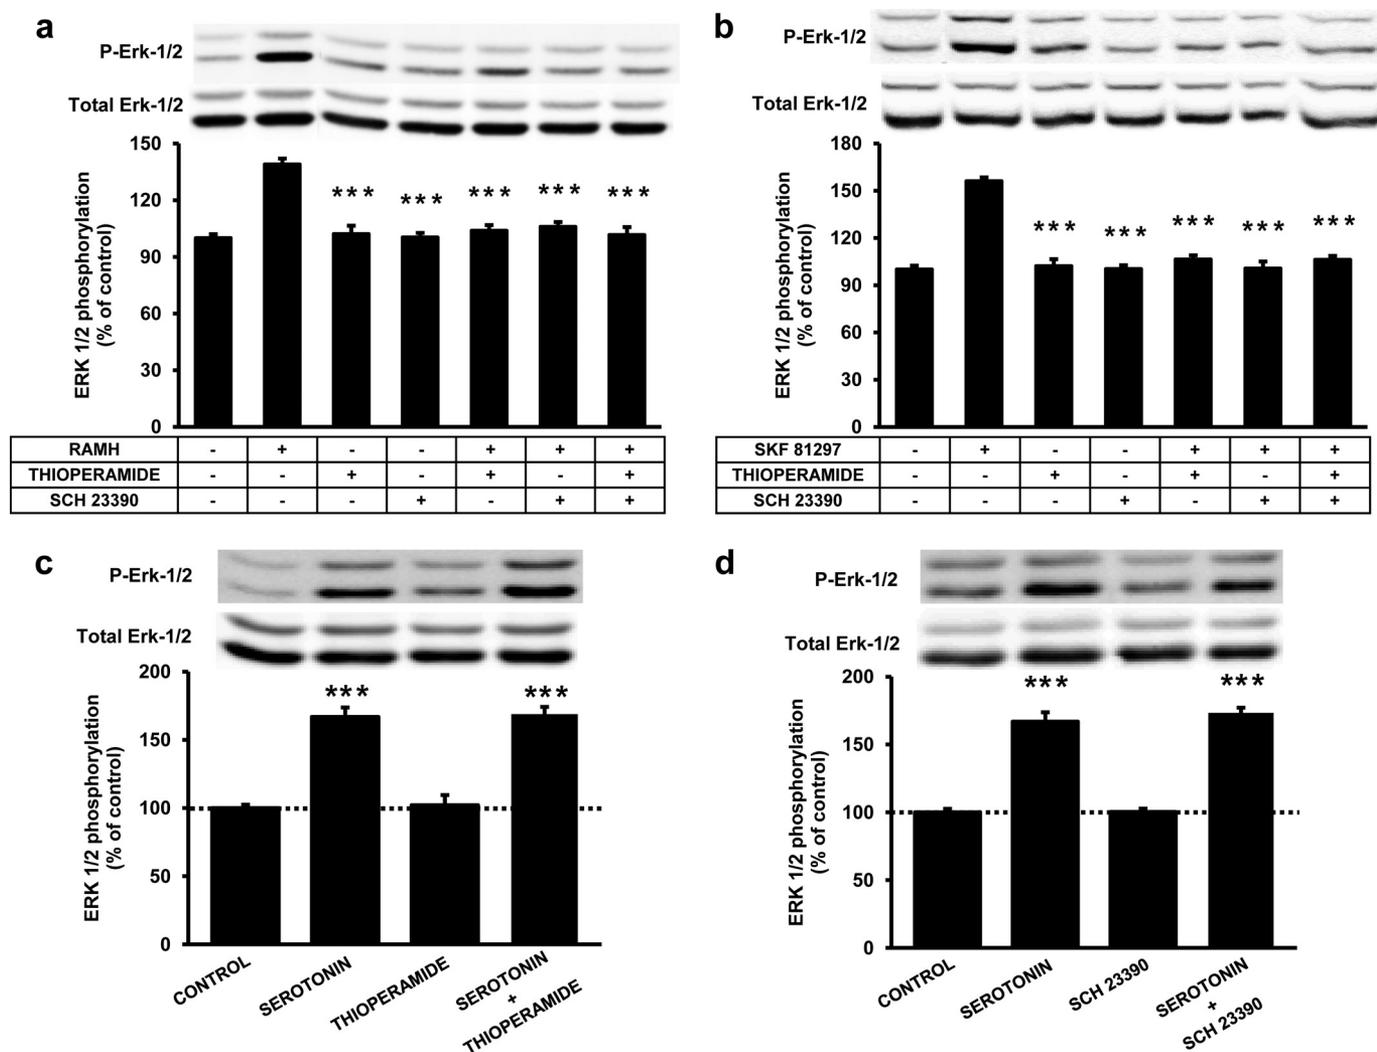

FIGURE 1.  $H_3$ R and  $D_1$ R agonists induced ERK 1/2 phosphorylation in rat striatal slices. *a*, slices were treated with 10  $\mu$ M SKF 38393 (black) or 1  $\mu$ M imetit (white). *b*, slices were treated for 10 min with different SKF 81297, SKF 38393, RAMH, or imetit concentrations. ERK 1/2 phosphorylation was determined as described under "Experimental Procedures." The immunoreactive bands from five to 27 (*a*) or 19 to 24 (*b*) slices obtained from three to 14 (*a*) or six to nine (*b*) animals were quantified, and values represent the mean  $\pm$  S.E. of the percentage of phosphorylation relative to basal levels of untreated slices (100%). Significant differences were calculated by one-way analysis of variance with post hoc Bonferroni's multiple tests and \*, \*\*, and \*\*\* correspond to  $p < 0.05$ ,  $p < 0.01$ , and  $p < 0.001$ , respectively, as compared with nontreated samples (control). A representative Western blot is shown in each panel (top).

*H<sub>3</sub>R* Agonist-induced ERK 1/2 Phosphorylation in Striatal Slices Is Mediated by  $D_1$ R- $H_3$ R Heteromers—A cross-antagonism between  $D_1$ Rs and  $H_3$ Rs has been demonstrated previously in heterologous cell systems. This cross-antagonism only occurs in  $D_1$ R- $H_3$ R-heteromer-containing cells and consists of both the ability of  $D_1$ R antagonists to block the effect of  $H_3$ R agonists and, conversely, the ability of  $H_3$ R antagonists to block the effect of  $D_1$ R agonists (15). To test whether this phenomenon also occurs *in vivo*, rat striatal slices were incubated with  $D_1$ R or  $H_3$ R agonists (SKF 81297 or RAMH, respectively) in the presence of either  $D_1$ R or  $H_3$ R antagonists (SCH 23390 or thioperamide, respectively). The results reproduced the cross-antagonism found in the heterologous cell system (Fig. 2). ERK 1/2 phosphorylation induced by RAMH (0.1  $\mu$ M) was not only blocked by thioperamide (10  $\mu$ M) but also by SCH 23390 (10  $\mu$ M) (Fig. 2*a*). Similarly, ERK 1/2 phosphorylation induced by SKF 81297 (0.1  $\mu$ M) was blocked by both SCH23390 and thioperamide (10  $\mu$ M in both cases) (Fig. 2*b*). As a control, activation of striatal serotonin receptors (with 0.2  $\mu$ M of serotonin) significantly induced ERK 1/2 phosphorylation, but the effect was not modified by either

SCH23390 or thioperamide (10  $\mu$ M in both cases) (Fig. 2, *c* and *d*). These results provide evidence for the expression  $D_1$ R- $H_3$ R heteromers in the striatum. Another characteristic of the  $D_1$ R- $H_3$ R heteromer is that it allows  $H_3$ R agonists to activate MAPK signaling (15). We decided to investigate whether this heteromer characteristic persisted *in vivo* using transgenic mice lacking  $D_1$ Rs. When  $H_3$ R-mediated MAPK signaling was investigated in striatal slices from transgenic mice lacking the  $D_1$ Rs and in wild-type littermate controls displaying the same genetic background, RAMH (0.1  $\mu$ M) was unable to induce ERK 1/2 phosphorylation, whereas a strong signal was obtained in slices from wild-type littermate controls displaying the same genetic background (Fig. 3). In addition in wild-type animals, RAMH-induced ERK 1/2 phosphorylation was blocked by both thioperamide (10  $\mu$ M) and SCH 23390 (10  $\mu$ M) (Fig. 3). These results indicate that  $H_3$ R agonist-induced ERK 1/2 phosphorylation in striatal slices is mediated by  $D_1$ R- $H_3$ R heteromers.

To provide further insight on the function of striatal  $D_1$ R and  $H_3$ R receptors coexpressed in striatal neurons, ERK 1/2

## Dopamine D<sub>1</sub>-histamine H<sub>3</sub> Receptor Heteromers in Striatum

**FIGURE 2. Effect of H<sub>3</sub>R and D<sub>1</sub>R antagonists on agonist-induced ERK 1/2 phosphorylation in rat striatal slices.** Slices were preincubated with medium or with 10  $\mu$ M thioperamide, 10  $\mu$ M SCH 23390, or both for 20 min prior to the addition of 0.1  $\mu$ M RAMH (a) or 0.1  $\mu$ M SKF 81297 (b) followed by a further incubation of 10 min. In c and d, slices were preincubated for 20 min with medium or with 10  $\mu$ M thioperamide (c) or 10  $\mu$ M SCH 23390 (d) prior to the addition of 0.2  $\mu$ M serotonin followed by a further incubation of 10 min. ERK1/2 phosphorylation was determined as described under "Experimental Procedures." The immunoreactive bands from 12 to 21 (a and b) or 10 to 14 (c and d) slices obtained from 8 to 10 (a and b) or 4 to 6 (c and d) animals were quantified, and values represent the mean  $\pm$  S.E. of the percentage of phosphorylation relative to basal levels found in untreated slices (100%). Significant differences were calculated by one-way analysis of variance with post hoc Bonferroni's multiple tests (\*\*\*,  $p < 0.001$ , as compared with the first treatment in a and b, or to the basal in c and d). A representative Western blot is shown in each panel (top).

activation was studied in rat striatal slices in the presence of agonists for the two receptors. This would mimic the situation when the two neurotransmitters histamine and dopamine are simultaneously impacting a given GABAergic neuron. Interestingly, the effect of the D<sub>1</sub>R agonist SKF 81297 (10  $\mu$ M) was significantly counteracted by the H<sub>3</sub>R agonist, RAMH (1  $\mu$ M). Furthermore, the combination of RAMH (10  $\mu$ M) and SKF 81297 (1  $\mu$ M) produced a significantly weaker effect than that of either drug alone (Fig. 4), indicating the existence in striatal neural circuits of an agonist-induced D<sub>1</sub>R-H<sub>3</sub>R reciprocal negative cross-talk.

**Selective D<sub>1</sub>R-H<sub>3</sub>R Heteromer-mediated Effects only in Striatal Neurons of Direct Pathway**—Dopamine receptors are segregated in the two main types of GABAergic striatal efferent neurons: dynorphinergic neurons of the direct pathway expressing D<sub>1</sub>Rs and enkephalinergic neurons of the indirect pathway expressing dopamine D<sub>2</sub>Rs. Evidence supporting the

presence of H<sub>3</sub>R in both types of neurons had been obtained previously by autoradiography and lesion studies (5) and by *in situ* hybridization (10). Accordingly, by double immunohistochemistry using H<sub>3</sub>R and either D<sub>1</sub>R or D<sub>2</sub>R antibodies, we found H<sub>3</sub>R immunostaining in cells labeled with either D<sub>1</sub>R or D<sub>2</sub>R antibodies (Fig. 5). In fact, 95  $\pm$  12% of D<sub>1</sub>R stained neurons or 89  $\pm$  15% of D<sub>2</sub>R stained neurons showed H<sub>3</sub>R staining (Fig. 6a). Thus, co-expression of D<sub>1</sub>R and H<sub>3</sub>R in GABAergic neurons of the direct pathway and co-expression of D<sub>2</sub>R and H<sub>3</sub>R in GABAergic neurons of the indirect pathway was found. We have described previously that both D<sub>1</sub>R and D<sub>2</sub>R may form heteromers with H<sub>3</sub>R in living cells (14, 15). To test D<sub>1</sub>R-H<sub>3</sub>R and D<sub>2</sub>R-H<sub>3</sub>R heteromer expression in the rat striatum, co-immunoprecipitation experiments were carried out. The immunoprecipitates with the anti-D<sub>1</sub>R antibody (Fig. 7a) or with the anti-D<sub>2</sub>R antibody (Fig. 7b) were not stained in a Western blot using anti-D<sub>2</sub>R or anti-D<sub>1</sub>R anti-

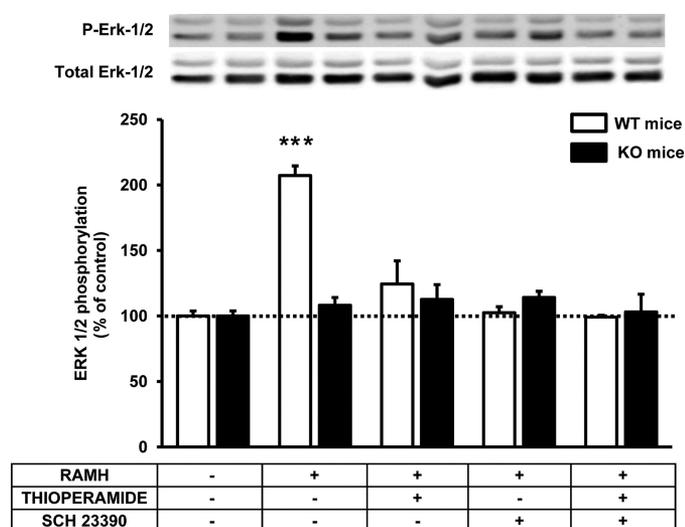

bodies respectively, showing the specificity of the antibodies. Interestingly, specific H<sub>3</sub>R staining was detected by Western blot in both immunoprecipitates using anti-D<sub>1</sub>R or anti-D<sub>2</sub>R antibodies but not with an irrelevant antibody (Fig. 7c). These

results corroborate the expression of D<sub>1</sub>R-H<sub>3</sub>R heteromers in the neurons of the direct pathway and suggest the expression of D<sub>2</sub>R-H<sub>3</sub>R heteromers in the neurons of the indirect pathway.

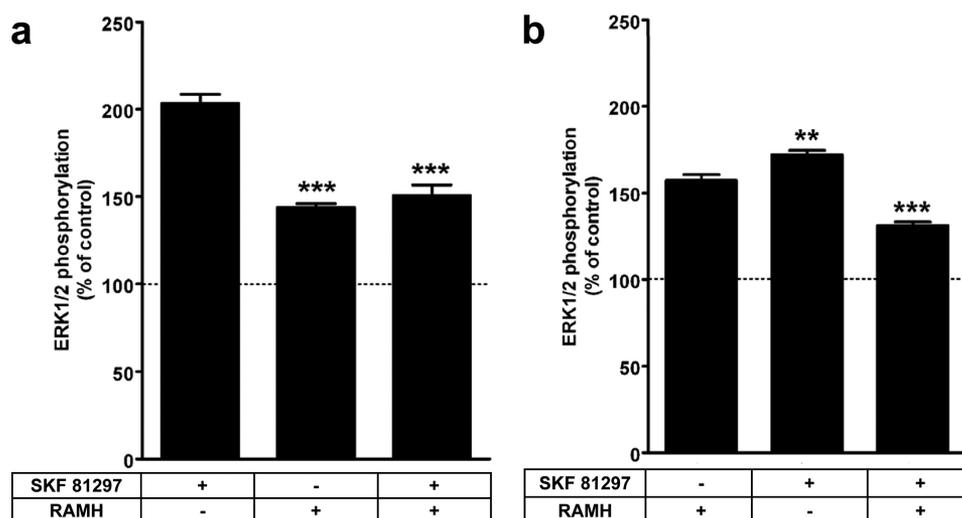

In striatal slices incubated with 1  $\mu$ M imetit and subjected to immunohistochemistry, we observed that imetit-induced ERK 1/2 phosphorylation occurs in a high number of neurons stained using the anti-D<sub>1</sub>R antibody, but only in a small number of neurons stained using the anti-dopamine D<sub>2</sub>R antibody (Fig. 8). In fact, 85  $\pm$  7% of phospho-ERK 1/2-positive neurons displayed specific D<sub>1</sub> receptor immunostaining, whereas only 23  $\pm$  5% of phospho-ERK 1/2-positive neurons were positive for D<sub>2</sub> receptor labeling (Fig. 6b). It should be noted that despite D<sub>2</sub>R-H<sub>3</sub>R heteromers may play a role in this signaling pathway, neurons containing both the D<sub>1</sub>R and D<sub>2</sub>R may exist in the striatum (18). Similar results were obtained in striatal slices incubated with 1  $\mu$ M RAMH (results not shown). Furthermore, the effect of H<sub>3</sub>R agonists in striatal slices was independent of changes in presynaptic neurotransmitter release (e.g. dopamine or histamine), which could potentially contribute to trigger ERK 1/2 phosphorylation in D<sub>1</sub>R-expressing cells. In fact, the presence of 1  $\mu$ M tetrodotoxin affected neither the D<sub>1</sub>R agonist nor the H<sub>3</sub>R agonist-induced ERK 1/2 phosphorylation (supplemental Fig. 1). Collectively, these results demonstrate that histamine-induced MAPK pathway activation in striatal slices is specifically mediated by the D<sub>1</sub>R and H<sub>3</sub>R heteromers present in neurons of the direct pathway, but not by the H<sub>3</sub>Rs localized in the indirect pathway or as autoreceptors or heteroreceptors in neighboring nerve terminals.

## DISCUSSION

We have previously described that not only D<sub>1</sub>R but also D<sub>2</sub>R may form heteromers with H<sub>3</sub>R in living cells (14, 15). Here, it is demonstrated that both D<sub>1</sub>R and D<sub>2</sub>R co-immunoprecipitate H<sub>3</sub>R from rat striatum supporting the expression

**FIGURE 3. H<sub>3</sub>R agonist-induced ERK 1/2 phosphorylation in striatal slices from wild-type and dopamine D<sub>1</sub>R knock-out mice.** Wild-type (white) or D<sub>1</sub>R knock-out mice (black) slices were treated for 10 min with 0.1  $\mu$ M RAMH or for 10 min with 10  $\mu$ M thioperamide and/or 10  $\mu$ M SCH 23390 prior to the addition of 0.1  $\mu$ M RAMH and incubation for further 10 min. ERK 1/2 phosphorylation was determined as described under "Experimental Procedures." For each treatment, the immunoreactive bands from four to six slices from a total six wild-type and nine knock-out animals were quantified, and values represent the mean  $\pm$  S.E. of the percentage of phosphorylation relative to basal levels found in untreated slices (100%). No significant differences were obtained between the basal levels of the wild-type and the D<sub>1</sub>R knock-out mice, and no significant differences were observed between basal and slices treated (20 min) with 10  $\mu$ M thioperamide or 10  $\mu$ M SCH 23390. Significant treatment and genotype effects were analyzed by a bifactorial analysis of variance followed by post hoc Bonferroni's tests. There were significant genotype, treatment, and interaction effects, explained by the ability of RAMH to strongly and selectively induce ERK 1/2 phosphorylation in wild-type mice (\*\*\*,  $p < 0.001$ , as compared with knock-out mice). A representative Western blot is also displayed (top).

**FIGURE 4. Negative cross-talk between D<sub>1</sub>Rs and H<sub>3</sub>R receptors on ERK 1/2 phosphorylation in rat striatal slices.** Slices were treated for 10 min with 10  $\mu$ M SKF 81297 and/or 1  $\mu$ M RAMH (a) or 10  $\mu$ M RAMH and/or 1  $\mu$ M SKF 81297 (b). ERK 1/2 phosphorylation was determined as described under "Experimental Procedures." The immunoreactive bands from 10 to 24 (a) or eight to 23 (b) slices obtained from four to six animals were quantified, and values represent the mean  $\pm$  S.E. of the percentage of phosphorylation relative to basal levels found in untreated slices (100%). Significant differences were calculated by one-way analysis of variance with post hoc Bonferroni's multiple tests. (\*\* and \*\*\*,  $p < 0.01$  and  $p < 0.001$ , respectively, as compared with 10  $\mu$ M SKF 81297 in (a) or 10  $\mu$ M RAMH in (b)).

## Dopamine D<sub>1</sub>-histamine H<sub>3</sub> Receptor Heteromers in Striatum

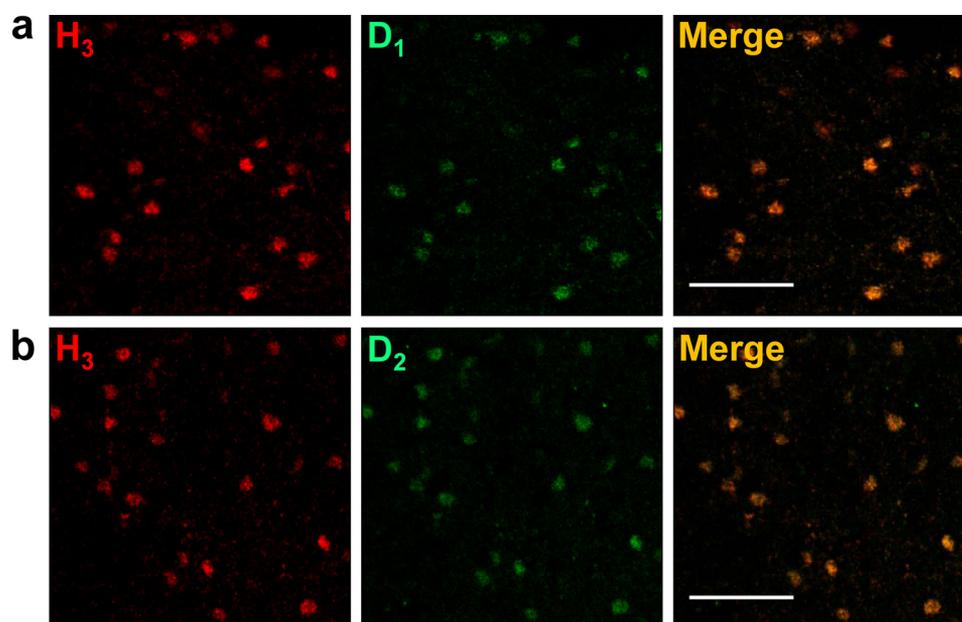

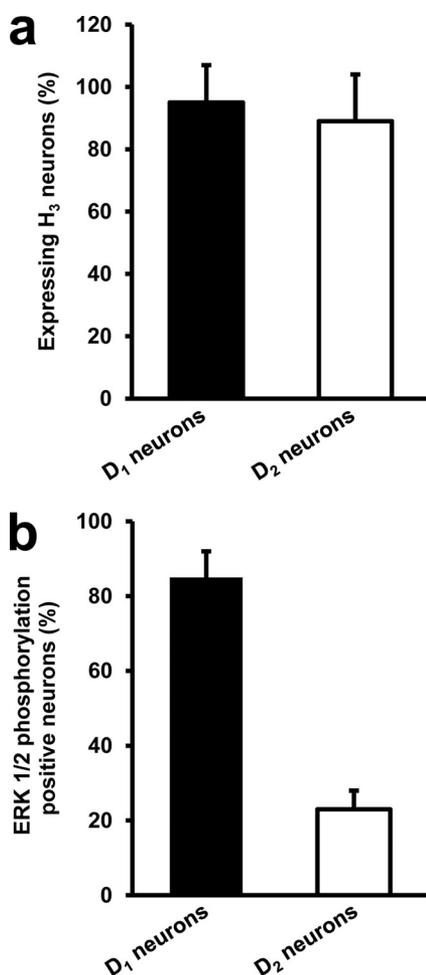

FIGURE 5. **Co-localization between H<sub>3</sub>R and D<sub>1</sub>R or D<sub>2</sub>R in striatal MSNs.** Confocal microscope representative images of coronal sections from striatal slices are shown. Slices were labeled with anti-H<sub>3</sub>R antibody (red). Labeling (green) using an anti-D<sub>1</sub>R antibody (a) or an anti-D<sub>2</sub>R antibody (b) is also shown. In a and b, colocalization is shown in yellow. Scale bars, 60  $\mu$ m.

of D<sub>1</sub>R-H<sub>3</sub>R and D<sub>2</sub>R-H<sub>3</sub>R heteromers in the neurons of the direct and indirect striatal efferent pathways, respectively. From our earlier work, it was unclear whether D<sub>1</sub>R-H<sub>3</sub>R and D<sub>2</sub>R-H<sub>3</sub>R heteromers were engaging similar signaling pathways in the two different neuronal populations or whether there was a functional difference that might help delineate the direct and indirect pathways of the striatum via the existence of these heteromers. The data presented in this paper indicate that D<sub>1</sub>R-H<sub>3</sub>R heteromers in the striatonigral GABAergic neurons of the direct pathway, but not the H<sub>3</sub>R receptors in the indirect pathway, allow direct histaminergic activation of the MAPK pathway.

Biophysical techniques can provide strong support for the existence of receptor heteromers in artificial cell systems (19, 20), but, as these techniques are difficult to perform in intact tissues, obtaining evidence for naturally occurring heteromer expression remains a significant challenge. For many receptor heteromers, we depend on an indirect approach for their identification in native tissues, which relies on the discovery of a characteristic signature of the heteromer. This characteristic, which is usually identified in a heterologous cell system, may be then used as a “fingerprint” to demonstrate the presence of the heteromer in the native tissue (21–24). A specific characteristic of the D<sub>1</sub>R-H<sub>3</sub>R heteromer, previously identified in transfected cells is cross-antagonism (15), *i.e.* the ability of both D<sub>1</sub>R and H<sub>3</sub>R antagonists to block the effect of either D<sub>1</sub>R or H<sub>3</sub>R agonists. This phenomenon, in which an antagonist of one of the receptor units in the receptor heteromer blocks signaling originated by ligand binding to the other receptor unit in the heteromer, has also been observed with other receptor heteromers, such as the cannabinoid CB<sub>1</sub>-orexin OX<sub>1</sub> receptor heteromer (25). Significantly, the same D<sub>1</sub>R-H<sub>3</sub>R cross-antagonism on MAPK signaling, which was described in transfected cells (15), was observed in rat striatal slices (Fig. 2), strongly supporting the occurrence of D<sub>1</sub>R-H<sub>3</sub>R

heteromers in the rodent striatum. Of note, a further characteristic of the D<sub>1</sub>R-H<sub>3</sub>R heteromer is its ability to allow the activation of the MAPK cascade by H<sub>3</sub>R-selective agonists, which otherwise cannot drive this signaling pathway (15). In fact, H<sub>3</sub>R agonist-induced ERK 1/2 phosphorylation was demonstrated in striatal slices of wild-type but not of D<sub>1</sub>R knockout mice, indicating the occurrence of D<sub>1</sub>R-H<sub>3</sub>R heteromers in the rodent striatum. As the H<sub>3</sub>R agonist was unable to activate MAPK signaling in slices from D<sub>1</sub>R-deficient mice (Fig. 3) it is likely that only neurons containing both H<sub>3</sub>R and D<sub>1</sub>R are able to link histaminergic neurotransmission to the MAPK cascade. Interestingly, although H<sub>3</sub>R were found to be co-expressed with D<sub>1</sub>R- and D<sub>2</sub>R-containing neurons, the H<sub>3</sub>R-mediated phospho-ERK labeling only co-distributed with D<sub>1</sub>R- but not with D<sub>2</sub>R-containing neurons (Figs. 5 and 8) and was not dependent on neurotransmitter release from neighboring cells.

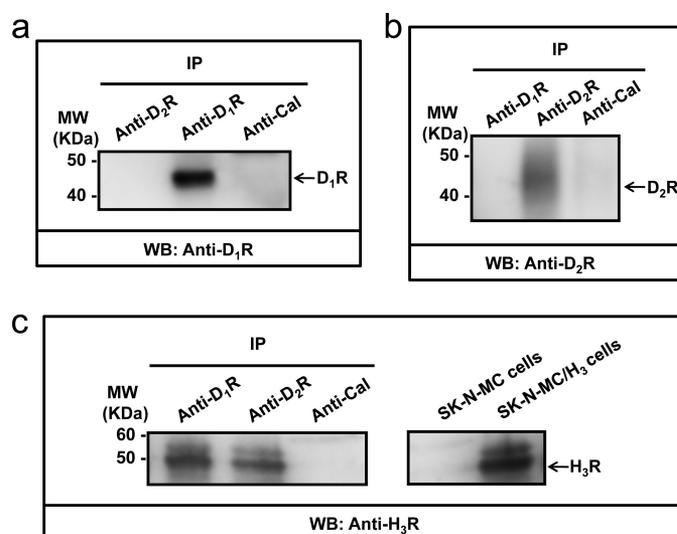

The results obtained with co-administration of D<sub>1</sub>R and H<sub>3</sub>R agonists suggest that the D<sub>1</sub>R-H<sub>3</sub>R heteromer works as a processor that integrates dopamine and histamine-related signals, and its output consists of quantitatively different activation of the MAPK pathway. Strong MAPK signaling was obtained with either D<sub>1</sub>R or H<sub>3</sub>R activation, but a significantly weaker MAPK signaling was obtained upon co-activation of both receptors. Thus, at very low dopamine concentrations, histamine can foster MAPK signaling by activating H<sub>3</sub>R in D<sub>1</sub>R-H<sub>3</sub>R-coexpressing neurons. In contrast, when the two neurotransmitters are present, the MAPK activation in the striatonigral MSN would be repressed. Because the MAPK pathway is considered critical to activity-dependent changes underlying synaptic strengthening (26), our results predict that not only dopamine but also histamine plays an important role in MAPK-dependent neuroplasticity in the striatonigral MSN.

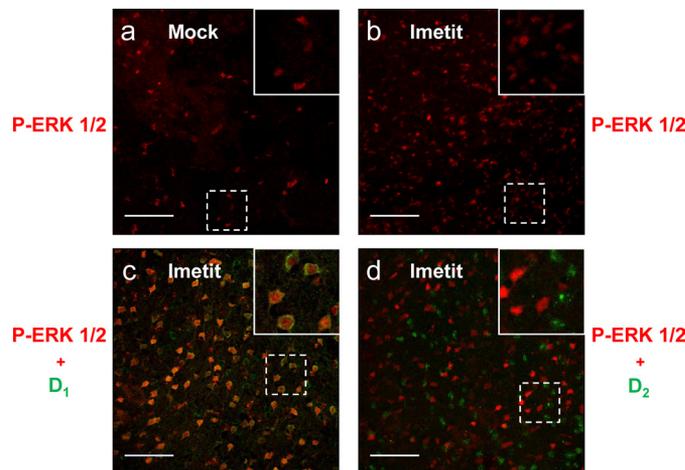

**FIGURE 6. Quantification of colocalization in confocal microscope images.** Quantification of H<sub>3</sub>R expression (a) or 1  $\mu$ M imetit-induced ERK 1/2 phosphorylation (b) in neurons expressing D<sub>1</sub>R (D<sub>1</sub> neurons) or D<sub>2</sub>R (D<sub>2</sub> neurons). Values are mean  $\pm$  S.E. of the percentage of double-labeled cells (cells stained for H<sub>3</sub>R and D<sub>1</sub>R or D<sub>2</sub>R in a or cells stained for imetit-induced phospho-ERK 1/2 and D<sub>1</sub>R or D<sub>2</sub>R in b) were counted in a total of two to three nonoverlapping fields of 15 (a) or 45 (b) coronal sections from four to five slices.

A negative cross-talk between striatal D<sub>1</sub>R and H<sub>3</sub>R has also been described for the adenylyl cyclase-induced signaling pathway, as histamine H<sub>3</sub>R activation inhibits D<sub>1</sub>R-mediated cAMP accumulation in striatal slices (27). Additional examples of H<sub>3</sub>R-mediated responses able to inhibit D<sub>1</sub>R-mediated effects are the ability of H<sub>3</sub>R agonists to inhibit the effects of D<sub>1</sub>R agonists on GABA release in striatal slices (12) and motor activation in reserpinized mice (14). Overall, these results are consistent with an antagonism at the level of adenylyl cyclase between H<sub>3</sub>R and D<sub>1</sub>R that would not require heteromer formation. In fact, it is known that H<sub>3</sub>R and D<sub>1</sub>R couple to G<sub>i</sub> and G<sub>s</sub>, respectively (9, 28–30). Although it is difficult to confirm these results in living animals, studies in transfected cells indicate that D<sub>1</sub>R-H<sub>3</sub>R heteromers couple to G<sub>i</sub>, but not to G<sub>s</sub>, to direct histaminergic input toward the MAPK pathway.

Taken together, it appears that histamine and dopamine antagonism mediated by D<sub>1</sub>Rs and H<sub>3</sub>Rs may rely on balancing ERK activation in GABAergic neurons where D<sub>1</sub>R and H<sub>3</sub>R are co-expressed and where D<sub>1</sub>R-H<sub>3</sub>R heteromerization is likely occurring. Heteromers not only allow neu-

**FIGURE 7. Co-immunoprecipitation of H<sub>3</sub>R and D<sub>1</sub>R or D<sub>2</sub>R.** Rat striatal membranes were solubilized and processed for immunoprecipitation as described under “Experimental Procedures” using rat anti-D<sub>1</sub>R antibody, rabbit anti-D<sub>2</sub>R antibody, or rabbit anti-calnexin antibody as negative control. As positive controls and to test the specificity of dopamine receptors antibodies, immunoprecipitates were analyzed by SDS-PAGE and immunoblotted using guinea pig anti-D<sub>1</sub>R antibody (a) or guinea pig anti-D<sub>2</sub>R antibody (b). To test the co-immunoprecipitation, immunoprecipitates were blotted with goat anti-H<sub>3</sub>R antibody (c). The right panel in c corresponds to solubilized membranes from SK-N-MC and SK-N-MC/H<sub>3</sub> cells analyzed by SDS-PAGE and blotted with anti-H<sub>3</sub>R antibody to test the specificity of the antibody. IP, immunoprecipitation; MW, molecular mass.

**FIGURE 8. Imetit-induced ERK 1/2 phosphorylation in rat striatal GABAergic neurons.** Confocal microscopy images of coronal sections from striatal slices were treated with medium (a) or treated with 1  $\mu$ M imetit (b–d). Slices were labeled with antiphospho-ERK 1/2 antibody (red). Labeling (green) using an anti-D<sub>1</sub> receptor antibody (c), or an anti-D<sub>2</sub> receptor antibody (d) is also shown. Insets in c and d are 2 $\times$  magnification of the indicated parts of the figure. Scale bars, 100  $\mu$ m (a and b) or 80  $\mu$ m (c and d). Representative images of coronal sections are displayed.

rons to differentially “sense” a given neurotransmitter, but they serve to process the different signals impacting them at a given time frame (31, 32). Therefore D<sub>1</sub>R-H<sub>3</sub>R receptor heteromers would be actively involved in controlling the response of striatal neurons of the direct striatal efferent pathway. The qualitative and quantitative output on ERK 1/2 phosphorylation would largely depend on the concentrations of histamine and dopamine impacting neurons expressing D<sub>1</sub>R-H<sub>3</sub>R complexes.
