Abstract

Palaearctic species of *Periclistus* Förster has been systematically described, but a new inquiline gall-wasp, *Periclistus qinghainensis* sp. n., is described from China. This species was obtained from an unknown stem gall induced on *Rosa* sp. Diagnosis, distribution and biology of the new species are described in this paper. After examining the types of *P. idoneus* Belizin, 1973 and *P. capillatus* Belizin, 1968, it is concluded that *P. idoneus* belongs to genus *Aulacidea*, and *P. capillatus* is a valid species of *Periclistus*. A key to the Palaearctic *Periclistus* species is also given.

Keywords

Cynipidae, Gallwasp, inquiline, *Periclistus*, taxonomy, revision, China

Introduction

Synergini is an important tribe of the family Cynipidae (Hymenoptera) with a worldwide distribution. They are biologically characterized for being inquilines: although they have lost the ability to induce galls, they are still able to directly modify the gall tissue that surrounds them, inducing the characteristic nutritive tissue usually found in the larval chambers of the gall-inducers (Melika 2006). All inquilines are wholly phytophagous, some of them being lethal if they compete with the inducer for the food in the same larval chamber. This lifestyle represents a unilateral relationship only beneficial for the inquiline (Askew 1984).

The Synergini includes 186 species of inquilines grouped in nine genera (Pénzes et al. 2012). Six genera are inquilines of cynipid galls on Fagaceae (Agastoroxenia Nieves-Aldrey & Medianero, 2010, Ceroptries Hartig, 1840, Saphoncicus Dalla Torre & Kieffer, 1910, Synergus Hartig, 1840, Synophrus Hartig, 1843 and Ufo Melika & Pujade-Villar, 2005); species of Synophromorpha (Ashmead, 1903) are also found in Diastrophus galls on Rubus (Rosaceae); Rhoophilus inquilines are found in lepidopteran galls induced by a Scyrotis moth (cecidiosid) on species of Rhus (Anacardiaceae); and inquilines of Periclistus Förster are associated with cynipid galls on roses (Diplolepidini).

Despite being morphologically similar to Synophromorpha Ashmead, Periclistus can be distinguished by the following characters (Ritchie and Shorthouse 1987): uniformly and delicately coriaceous mesoscutum (graniculate or smooth in Synophromorpha); notauli never complete, forming two short sulci not posteriorly broadened (complete and distinctly broadened notauli in Synophromorpha), ventral margin of subalar triangle with a row of setigerous punctures (without a row of setigerous punctures in Synophromorpha), closed radial cells (opened radial cells in Synophromorpha and Japanese species of Periclistus), and the male’s third flagellomere usually strongly notched and distally broadened (third flagellomere weakly curved, broadly notched and weakly expanded distally in Synophromorpha). Both genera form a monophyletic group, as has been demonstrated by several authors (Ritchie and Shorthouse 1987; Ronquist and Liljeblad 2001; Nylander 2004, among others). Here genus Periclistus is firstly reported from China, with a new species Periclistus qinghainensis sp. n., found in a gall on an unidentifies species of Rosa induced by an unknown species in Diplolepis.

Materials and methods

The types of P. idoneus and P. capillatus described by Belizin from Hurfeish (Israel) and Primorskij Kraj (Russian Far East) respectively, have been examined in this study.

* In the moment to publish this manuscript the Synergini is reestructred according to Ronquist et al. (2015)
They are deposited in ZIN (Zoological Institute of the Russian Academy Sciences, St. Petersburg, Russia).

The galls of the new species described here were collected on May 2010 in the north western province of Qinghai of China. During this month the weather is still cold, the branches of trees are still covered by snow and the useful characters to determine the *Rosa* species are not present in the plant, so it was impossible to identify it; in addition, in China there are approximately 100 described species of *Rosa*, making it hard to establish a potential candidate. Hence, the galls were sent to Y. Wang without determination of *Rosa* species.

The current terminology describing the cynipid gall-wasp morphology follows Liljeblad and Ronquist (1998) and Melika (2006). Abbreviations for the forewing venation are taken from Ronquist and Nordlander (1989) and those for the cuticular surface from Harris (1979). Measurements and abbreviations used here include F1–F12 for first and subsequent flagellomeres. Other abbreviations are: post-ocellar distance (POL), the distance between the inner margins of the posterior ocelli; ocellar–ocular distance (OOL), the distance from the outer edge of the posterior ocellus to the inner margin of the compound eye; and lateral-ocellar distance (LOL), the distance between lateral and frontal ocelli. The width of the forewing radial cell was measured from the margin of the wing to the Rs vein.

Measurements were made under a Leica MZ 12.5 stereomicroscope (Wetzlar, Germany), and photos were taken with a digital camera (Q-Imaging, Micropublisher 3.3 RTV) attached to the Leica MZ APO stereomicroscope (Wetzlar, Germany) using software of Synoptics Auto-Montage version 5.0.

Specimens of the new species are deposited in the Hymenoptera Collection in Zhejiang A & F University (ZAFU) and the University of Barcelona (UB), respectively.

**Results**

*Periclistus capillatus* Belizin, 1968

**Diagnosis.** This species is characterized by the following characters: black head and mesosoma, chestnut brown to black metasoma, testaceous antennae and legs; 12-segmented antenna, F1 and F2 subequal in length (4:5); an alutaceous mesoscutum with
piliferous points and sparse pubescence; notaui and posterior medial sulcus present, short, both extending to ¼ of total scutum length; parapsidal lines and anterior parallel lines present; smooth mesopleuron; closed radial cell (although both R1 and its projection in margin of forewing nearly inconspicuous), short, 3 times as long as broad; areola visible; metasomal tergites fused (T2+T3) and smooth, with an anterolateral patch of white setae; the subsequent segments are micropunctuated and glabrous.

**Comments.** This species presents characters belonging to Asian species (scutal and mesopleural sculpture) and characters belonging to European species (radial cell length and shape). A key provided at the end differentiates this species from its congener.

*Aulacidea idoneus* (Belizin, 1973), comb. n.

**Type material.** 1 ♀ deposited in ZIN, with the following labels: Herfeish, 22.IV, Israel, V. Trjapitzin ‘966” (black label, handwritten in Russian), “Holotype *Periclistis idoneus* ♀ m., V. Belizin det” (red label, handwritten), *Aulacidea idoneus* Belizin, 1973, det. JP-V 2015” (white label, printed).

**Comments.** After examining the holotype, we conclude that this species belongs to genus *Aulacidea*. After determining the specimen following the Palaearctic *Aulacidea* species key made by Melika (2006) we conclude that this species is a valid species related to *A. laureae* Nieves-Aldrey, 1992 and *A. follioti* Barbotin, 1972. The three species present the head broader than high, 13-segmented antenna, F1 shorter than F2, incomplete notaui and ciliated forewing margin. *Aulacidea idoneus* differs from *A. follioti* in presenting median mesoscutal line, like *A. laureae*; *A. idoneus* can be distinguished from *A. laureae* by the following characters: short and narrow scutelar foveae, OOL 3.0 times longer than the diameter of lateral ocellus, space between totuli and clypeus without radiating carina, having shorter notaui and medial mesoscutal line shorter (both extending 1/3 of scutum length) and radial cell (slightly more than 2.0 times longer than broad) and having a second metasomal tergite with only some dorsal points while being laterally smooth.

*Periclistus mongolicus* Belizin, 1973, species dubia

**Remarks.** This species described from Mongolia was considered by Abe et al. (2007) as having an uncertain status until the types were revised. Because of the loss of the type material (S. Belokobylskij pers. comm.) this species is definitively considered as ‘*species dubia*’ according to the description, which does not permit assessment of its validity nor its placement in the genus *Periclistus*. 
Periclistus qinghainensis sp. n.
http://zoobank.org/C0EA8F5E-6EAB-4B2F-B77B-1F97332B6066
Figs 1–2

Diagnosis. Periclistus qinghainensis sp. n. differs from all of the known Periclistus species in the absence of notauli. Periclistus qinghainensis sp. n. is morphologically similar to two Japanese species (P. natalis Taketani & Yasumatsu and P. quinlani Taketani & Yasumatsu) and the Far East Russian species (P. capillatus) in having a smooth and shiny mesoscutum (very weakly alutaceous in P. capillatus) with dispersed piliferous points and smooth mesopleuron, but it differs from all these species in having a partially closed radial cell (radial cell opened in P. natalis and P. quinlani while closed and shorter in P. capillatus), shorter F1 than F2 (F1 and F2 subequal in P. natalis and P. quinlani) and the absence of notauli (present in the other three species). Periclistus qinghainensis sp. n. differs from the European species in having the radial cell partially closed (closed in P. caninae (Hartig) and P. brandtii Ratzeburg), a smooth and shiny mesoscutellum (uniformly and delicately coriaceous scutellum with a dense and short pilosity without piliferous points in the European species) and the length and width of the radial cell (more than 4.0 times as long as wide in P. qinghainensis while around 3.0 times in P. brandtii and P. caninae).

Description. Length. Female. Body length 2.1 mm, and fore wing 2.8 mm.

Colour. Body black, except yellow tegulae and antennae, scapus and apical flagellomere darker; coxae dark brown, rest of the legs yellowish; forewing hyaline, with brown veins.

Head (Fig. 1a, b). Head coriaceous, with sparse setae, 2.0 times wider than long in dorsal view, 1.4 times wider than high in front view and slightly wider than mesosoma. Gena delicately coriaceous and not broadened behind eyes. Clypeus very small, impressed quadrangular and delicately coriaceous, ventrally slightly rounded; slightly higher than wide, with distinct small anterior tentorial pits, epistomal sulcus and clypeo-pleurostomal lines indistinct. Lower face with striae radiating from clypeus, not reaching eyes and antennal socket, median elevated area delicately coriaceous and striated. Malar space 0.3 times longer than eye height. Diameter of antennal torulus 2.0 times longer than inter-toruli distance and 1.1 times longer than eye-torulus distance. POL: OOL: LOL=1.7: 0.6: 1.3. Frons, vertex, and gena behind eyes and postgena with sparse setae. Frons largely smooth, with some very small and distinct punctures but without lateral frontal carina. Vertex and occiput uniformly punctured.

Antenna. Female (Fig. 2a). 12-segmented, slightly shorter than body; pedicel subglobose, only slightly longer than wide; F1 2.5 times as long as pedicel; F2 around 1.2 times as long as F1 and only slightly longer than F3; the antennal formula is: 9: 4: 10: 13: 11: 11: 10: 9: 8: 7: 14. Male (Fig. 2b, c). antenna 14- segmented, F1 medially incised and apically swollen, 2.3 times as long as pedicel, 0.9 times as long as F2; F2 as long as F3; F4 slightly longer than F3; F6–F8 equal in length; F9-10 equal in length; the antennal formula is: 3.0: 2.0: 4.2: 4.9: 5.0: 5.5: 5.0: 4.5: 4.5: 4.5: 4.0: 4.0: 3.5: 4.0.
Figure 1. *Periclistus qinghainensis* sp. n.: a head of female in front view b head of female in dorsal view c head and mesoscutum of female in dorsal view d general habitus of female in lateral view.

**Mesosoma** (Fig. 1c, d). Mesosoma slightly compressed dorso-ventrally and longer than high in lateral view, and with white setae. Pronotum dorsal an lateral surface uniformly and delicately coriaceous, lacking wrinkles and lateral pronotal carina but having rounded anterior corners in dorsal view. Mesoscutum smooth and shiny with some dispersed piliferous points, slightly broader than long. Notauli and median mesoscatal line absent; anterior parallel lines distinct, extending to 1/4 of entire mesoscutum length. Parapsidal lines present, shallow, extending to 1/4 of mesoscutum length.
Mesoscutum rugose, more sculptured toward central scutellar disk and between scutellar foveae, metanotum slightly overhanging. Scutellar foveae transversely ovate, only slightly wider than high, well-delimited around, with smooth and shiny deep bottom but without setae, separated by distinct medial carina. Mesopleuron smooth and shiny,
without striae, with dense setae ventrally, especially postero-ventrally; mesopleural triangle alutaceous, with sparse setae. Metapleural sulcus reaching the mesopleuron at 4/5 of its height; lateral propodeal carinae straight and parallel, with some setae; central propodeal area coriaceous, with setae; lateral propodeal area uniformly and delicately coriaceous, with relatively dense white setae.

**Fore wing** (Fig. 2d–f). Forewing longer than body, wing margin with long cilia; radial cell 4.3 times as long as the wide, partially closed (R1 vein projected about 1/3-1/2 on radial cell margin), Rs and R1 veins slightly curved, areolet distinct; vein Rs+M distinct, nearly reaching basalis.

**Metasoma. Female** (Fig. 1d). Metasoma nearly as long as head plus mesosoma, distinctly longer than height in lateral view; metasomal tergites 2+3, with patches of dense setae at laterals in its base, fifth and sixth metasomal tergites broadly punctuate dorso-posteriorly; prominent part of ventral spine of hypopygium very short. **Male.** Second and third metasomal tergites not fused, separated by a suture.

**Type material examined.** Holotype. ♀, China: Qinghai, Huzhu, Bei Mountain (102°32’E, 36°51’N), 2010-V-6, Guo Rui, reared in galls on *Rosa* sp. Paratypes. 6♀♀1♂, same labels as the holotype (1♀ paratype UB).

**Distribution.** China (Qinghai).

**Biology.** Reared from stem galls on *Rosa* sp. (Fig. 1g and h). The young gall is juicy, soft, covered with small raised tubercles, and multilocular with greenish-purple spots, 1.0-2.0 cm in diameter. Adults emerge in September.

**Etymology.** The new species is named after the province where it was collected.

**Discussion**

*Periclistus* includes 12 species in the Holarctic region, seven species known from America to the north of Mexico (*P. arefactus* McCracken & Egbert; *P. californicus* Ashmead; *P. obliquus* Provancher; *P. piceus* Fullaway; *P. pirata* (Osten Sacken); *P. semipiceus* (Harris); and *P. smilacis* (Ashmead) (Burk 1979; Ritchie and Shorthouse 1987)); two (Fig. 3) from the western Palearctic (*P. brandtii* (Ratzeburg) and *P. caninae* (Hartig)); and three (Fig. 3) from the eastern Palearctic: *P. capillatus* Belizin from Russian Far East, *P. natalis* Taketani & Yasumatsu and *P. quinlani* Taketani & Yasumatsu from Japan (Belizin 1973; Taketani and Yasumatsu 1973).

*Periclistus* species are associated with *Diplolepis* and *Liebelia* galls, except *P. smilacis*, a Nearctic species known from Florida reared in galls of *Diastrophus smilacis* (Ashmead 1896; Penzes et al. 2012), although M. Buffington and M. Gates (pers. comm.) disagree and consider *P. smilacis* should be associated with some *Diplolepis* species.

Abe et al. (2007) placed *Periclistus capillatus* and *P. mongolicus* in an ‘uncertain status’ and the original description of *P. idoneus* does not allow one to discriminate this species from *P. caninae* and *P. brandtii*, except for the shorter radial cell present in *P. idoneus*. After examining the type material of *Periclistus capillatus* we considered it is a valid species. Unfortunately, the type material of *P. mongolicus* is lost, so we were not
able to study it and we considered this species ‘incertae sedis’. Finally, when examining the holotype of *P. idoneus* we concluded that it was a valid species belonging to the genus *Aulacidea*.

*Periclistus natalis* and *P. quinlani* are morphologically very similar (both having complete shallow notauli, smooth and shiny mesopleuron, and opened radial cell of the forewing), and share the same gall host (*Diplolepis japonica* (Walker)) and host plant (*Rosa polyantha* Sieb. & Zucc.); however, the authors of these species (Taketani and Jasumatzu 1973) described biological differences between them. Abe (1998) studied the type material of these two species and concluded that there was only one morphological character different between the two species, viz. the pits of the notauli are weakly present anteriorly in *P. natalis*, and absent in *P. quinlani*. Nevertheless, this difference is very superficial based on our knowledge of morphology of Cynipidae; with additional data, it is very probable that both species will be synonymized.

The species described here, *Periclistus qinghainensis*, is similar to two Japanese species (*P. natalis* and *P. quinlani*) and a Far Eastern Russian species (*P. capillatus*). They share a punctured mesoscutum and smooth and shiny mesopleuron. These characters are exclusive of these four species from the rest of the Eastern Palaearctic *Periclistus*. *Periclistus qinghainensis* presents a partially closed radial cell, an intermediate characteristic between the open radial cell of the Japanese species and the remaining of Palaearctic species (*P. caninae* and *P. brandtii* both present a closed radial cell). As mentioned above, *P. capillatus* is intermediate between the Japanese and Chinese species and the remaining of Palaearctic species

**Key to Palaearctic species of Periclistus**

1 Mesopleuron entirely smooth, shiny, without striae; mesoscutum smooth or alutaceous, shiny, with sparse setae and piliferous points.........................2
Mesopleuron with more or less delicate striae; mesoscutum dull and uniformly coriaceous, with dense setae.................................5

2 Forewing with the radial cell partially closed (Fig. 2e–f); notauli absent (Fig. 1c); metasoma black in females........................... P. qinghainensis sp. n.

– Forewing with radial cell opened or closed; notauli shallow but distinct; metasoma reddish-brown in females .................................................................3

3 Radial cell short, around 3.0 times as long as the width; forewing hyaline ....
......................................................................................... P. capillatus Belizin, 1968

– Radial cell longer, around 4.0 times as long as the width; forewing with small clouded macula posterior to anterior margin near apex of radial cell .......... 4

4 Notaular pits present anteriorly but weakly impressed; and metasoma reddish-brown .................................................. P. natalis Taketani & Jasumatsu, 1973

– Notaular pits absent; and metasoma blackish brown.......................... P. quinlani Taketani & Jasumatsu, 1973

5 Notauli complete; mesopleuron entirely striated, without smooth and shiny patch; fused second and third metasomal tergites of females and third metasomal tergite in males without punctuation or only with some punctures in dorso posterior part................................. P. brandtii Ratzeburg, 1831

– Notauli incomplete, absent or very indistinct in the anterior half; mesopleuron mainly striate but with a smooth and shining patch posteriorly; the fused second and third metasomal tergites of females and third metasomal tergite in males with a narrow band of punctuation in posterior part.................. P. caninae (Hartig, 1840)

Acknowledgements

We would like to thank Sergey Belokobylnskij and Oleg Kovalev (ZIN) who sent us the types specimens from Belizin and for translating their labels to English. The project was supported by the Natural Science Foundation of China (31472032 and 31071970) and Zhejiang Provincial Natural Science Foundation for Distinguished Young Scholars (LR14C040002), Science Foundation of Zhejiang A & F University and a scholarship under the Zhejiang Association for International Exchange of Personnel.
