40 **ABSTRACT**

41 A new family of “Fe<sup>II</sup>( $\eta^5$ -C<sub>5</sub>H<sub>5</sub>)” half sandwich compounds bearing a N-heteroaromatic ligand  
42 coordinated to the iron center by a nitrile functional group has been synthesized and fully characterized  
43 by NMR and UVeVis spectroscopy. X-ray analysis of single crystal was achieved for complexes 1 and  
44 3, which crystallized in the monoclinic P2<sub>1</sub>/c and monoclinic P2<sub>1</sub>/n space groups, respectively. Studies  
45 of interaction of these five new complexes with plasmid pBR322 DNA by atomic force microscopy  
46 showed very strong and different types of interaction. Antiproliferative tests were examined on human  
47 leukemia cancer cells (HL-60) using the MTT assay, and the IC<sub>50</sub> values revealed excellent  
48 antiproliferative activity compared to cisplatin.

## 49 1. Introduction

50

51 Organometallic chemistry emerged in the recent years as an  
52 attractive field for the search of new compounds as potential drugs  
53 for medicinal chemistry, in particular for chemotherapy. In this  
54 frame, metallocene derivatives have appeared at the end of the  
55 1970s with the pioneering work of Köpf and Köpf-Maier involving  
56 the antitumor activity of early transition-metal cyclopentadienyl  
57 complexes [1]. The promising results obtained for dichloride metallocenes  
58 ( $\text{Cp}_2\text{MCl}_2$ , where  $\text{M} = \text{Ti, V, Nb, Mo}$ ;  $\text{Cp} = \eta^5\text{-cyclopentadienyl}$ )  
59 showing antitumor activity against numerous tumors,  
60 such as Ehrlich ascites tumor, B16 melanoma, colon 38 carcinoma  
61 and Lewis lung carcinoma, as well as against several human tumors  
62 heterotransplanted to athymic mice, certainly constitute an  
63 important impulsion for the interest of this area [2]. Titanium  
64 dichloride,  $(\eta^5\text{-C}_5\text{H}_5)_2\text{TiCl}_2$ , was the first of such species in clinical  
65 trials [3]. Nevertheless, problems related with formulation led to  
66 the abandonment of titanocene dichloride in Phase II clinical trials  
67 [4 -6]. Ferrocene derivatives also appeared with promising results  
68 showing activity against Rauscher leukemia virus and EAT in CF1  
69 mice [7,8] and in P388 leukemia cells [9] reinoculated tumors [10].  
70 Particularly, the ferrocifens family, which is a ferrocene derivative  
71 of tamoxifen (Astra Zeneca, London, UK e the drug used for treating  
72 breast cancer), has revealed good cytotoxicity activities. However,  
73 these molecules suffer from poor bioavailability restricting them  
74 from entering clinical trials. In order to overcome this limitation  
75 and advance toward clinical studies, several formulations are being  
76 tested, such as nanoparticles, lipid nanocapsules and cyclodextrins  
77 [11].

78

79

80

81 The half-sandwich family of compounds emerged more recently  
82 using different central metals and has revealed potentialities as  
83 anticancer drugs. The particular geometry of piano stool compounds  
84 provides a good scaffold for building new molecules by  
85 changing the coordinated arene, which can be  $\eta^6$  or  $\eta^5$ -bonded, the  
86  
87  
88  
89 chelated active ligand and also the coligands. In this context,  
90  $[\text{Ru}(\eta^6\text{-arene})(\text{X})(\text{Y-Z})]$  complexes (where Y-Z is a chelating  
91 ligand, and X is monoanionic ligand) revealed high cytotoxicity  
92 against human ovarian tumor cells [12 -15] and they are thought to  
93 act through covalent Ru-DNA interactions [16,17]. Related compounds  
94 incorporating the 1,3,5-triaza-7-phosphaadamantane  
95 (PTA) ligand, such as  $[\text{Ru}(\eta^6\text{-p-cymene})(\text{PTA})\text{Cl}_2]$  (RAPTA-C), have  
96 shown activity against metastases and although their mechanism  
97 of action has not been established, a pH dependent interaction with  
98 DNA may be a key component [18]. During the last years, our  
99 research group has been exploring a third family of half-sandwich  
100 compounds based on the “ $\text{Ru}^{\text{II}}(\eta^5\text{-C}_5\text{H}_5)$ ” fragment, with the general  
101 formula  $[\text{Ru}(\eta^5\text{-Cp})(\text{P-P})(\text{L})][\text{X}]$  (where P-P is a chelating  
102 phosphane or two phosphane ligands, L is a N-heteroaromatic  
103 sigma ligand mono or bidentate ligand and X is a counterion) [19 -  
104 24]. Our studies showed significant toxicity for a variety of cancer  
105 cell lines, namely LoVo and HT29 human colon adenocarcinoma,  
106 MiaPaCa pancreatic cancer cell lines, HL-60 human leukemia cancer  
107 cells, A2780 human ovarian cancer cells (and the resistant form  
108 A2780CisR), MCF7 and MDAMB231 human breast cancer cells  
109 (estrogen dependent and independent, respectively) and PC3 human  
110 prostate cancer cells, with  $\text{IC}_{50}$  values lower than those of  
111 cisplatin in most cases [19 -24]. One important advantage of

112 ruthenium based compounds for therapeutic uses compared to  
113 other metal complexes, is pointed out on its ability to mimic iron in  
114 binding biologically relevant molecules such as albumin and  
115 transferrin and consequently to show much lower toxicity than  
116 that of platinum therapies [25]. The success of the coordination of  
117 N-heteroaromatic ligands to the fragment 'RuCp' in terms of finding  
118 new compounds with important cytotoxicity against several cancer  
119 cell lines led us to extend our studies to the analog 'FeCp' derivatives.  
120 In this context, we have recently published our first results  
121 concerning a new family of compounds with the general  
122 cationic structure  $[\text{Fe}(\eta^5\text{-Cp})(\text{P-P})(\text{L})]^+$ , where L is coordinated to  
123 the iron center by the N atom of the heteroaromatic ligand [26].  
124 These new compounds showed values of cytotoxicity against MCF7  
125 and HeLa much lower than the ones found for cisplatin in the same  
126 experimental conditions.

127

128

129

130

131 Having in mind to exploit the effect of cytotoxicity of other  
132 ligands coordinated by a different group than a N-heteroaromatic  
133 atom, we had previously studied two new  $[\text{Ru}(\eta^5\text{-Cp})(\text{PPh}_3)_2(\text{N} \equiv \text{CL})]^+$   
134 derived compounds where  $\text{N} \equiv \text{CL}$  was coordinated  
135 by a nitrile functional group (benzo[1,2-b; 4,3-b']  
136 dithio-phen-2-carbonitrile and [5-(2-thiophen-2-yl)-vinyl]-thiophene-  
137 2-carbonitrile]) which were tested against HL-60 cells  
138 [20]. The  $\text{IC}_{50}$  values obtained after 24 h of incubation were  
139  $1.46 \pm 0.25$  and  $5.89 \pm 0.67$  mM, respectively, while cisplatin in  
140 the same experimental conditions presented a higher  $\text{IC}_{50}$  value  
141 of  $15.61 \pm 1.15$  mM. These motivating results obtained with  
142 ruthenium coordinated nitrile ligands together with our interest

143 to continue the exploitation of the cytotoxic properties of 'FeCp'  
144 compounds led us to the synthesis of a new family of iron nitrile  
145 compounds of general formula  $[\text{Fe}(\eta^5\text{-Cp})(\text{NCL})(\text{P-P})]^+$ . In the  
146 present paper we report the synthesis of compounds of the  
147 general formula  $[\text{Fe}(\eta^5\text{-Cp})(\text{NCL})(\text{P-P})]^+$ , where the NCL ligands,  
148 2-quinolinecarbonitrile (L1), 3-quinolinecarbonitrile (L2), 2-  
149 pyrazinecarbonitrile (L3) or 2,3-pyrazinedicarbonitrile (L4), present  
150 on their structures one or two N-heteroaromatic rings. These  
151 new compounds were fully characterized and their interaction  
152 with plasmid pBR322 DNA was studied by atomic force microscopy.  
153 Moreover, their potentialities as cytotoxic agents against  
154 human leukemia cancer cells (HL-60 cells) were evaluated.  
155 Remarkably, our studied compounds revealed  $\text{IC}_{50}$  values lower  
156 than those of cisplatin. Apoptotic behavior was also evaluated  
157 and compared with cisplatin.

158  
159

## 160 **2. Experimental**

### 161 2.1. General procedures

162 All syntheses were carried out under dinitrogen atmosphere using current Schlenk techniques and the  
163 solvents used were dried using standard methods [27].  $[\text{Fe}(\eta^5\text{-C}_5\text{H}_5)(\text{dppe})\text{I}]$  was prepared following  
164 the method described in literature [28]. FT-IR spectra were recorded in a Mattson Satellite FTIR  
165 spectrophotometer with KBr pellets; only significant bands are cited in text.  $^1\text{H}$ ,  $^{13}\text{C}$  and  $^{31}\text{P}$  NMR  
166 spectra were recorded on a Bruker Avance 400 spectrometer at probe temperature. The  $^1\text{H}$  and  $^{13}\text{C}$   
167 chemical shifts are reported in parts per million (ppm) downfield from internal  $\text{Me}_4\text{Si}$  and the  $^{31}\text{P}$  NMR  
168 spectra are reported in ppm downfield from external standard, 85%  $\text{H}_3\text{PO}_4$ . Elemental analyses were  
169 obtained at Centro de Apoio Científico Tecnológico Á Investigación (C.A.C.T.I.), at Universidade de  
170 Vigo, using a Fisons Instruments EA1108 system. Electronic spectra were recorded at room temperature  
171 on a Jasco V-560 spectrometer in the range of 200-900 nm.

172

### 173 2.2. Complexes synthesis

#### 174 2.2.1. General procedure applied to the synthesis of the complexes 1-5

175 To a stirred suspension of 0.5 mmol of  $[\text{FeCp}(\text{dppe})\text{I}]$  in dichloromethane (25 mL) was added 0.6 mmol  
176 of the adequate ligand (L1 = 2-quinolinecarbonitrile; L2 = 3-quinolinecarbonitrile; L3 = 2-  
177 pyrazinecarbonitrile; L4 = 2,3-pyrazinedicarbonitrile) followed by addition of 0.6 mmol of  $\text{TIPF}_6$  (for

178 complexes 1, 2, 3 and 4) or AgCF<sub>3</sub>SO<sub>3</sub> (for complex 3). After refluxing for a period of 5-6 h the color  
 179 changed from gray to orange reddish. The reaction mixture was cooled down to room temperature and  
 180 the solution was filtered to eliminate the TiCl<sub>4</sub> or the AgCl precipitate. The solvent was then removed  
 181 under vacuum and the residue was washed with n-hexane (2 x 10 mL). Dark red crystals were obtained  
 182 after recrystallization from dichloromethane/n-hexane solutions.

183 Compound 5 was obtained by stirring for 90 min, a suspension of 0.32 g (0.5 mmol) of [FeCp(dppe)I]  
 184 and TIPF<sub>6</sub> (0.21 g, 0.6 mmol), in dichloromethane (25 mL) to which a solution of 2,3-dicyanopyrazine  
 185 in dichloromethane (0.078 g; 0.6 mmol) was slowly added. The obtained purple solution was dried and  
 186 washed with n-hexane, giving a powder, which after recrystallization from dichloromethane/n-hexane,  
 187 gave needle shaped purple crystals.

188

246

247 2.3. Crystal structure determination of *[FeCp(dppe)(2-cq)][PF<sub>6</sub>]* 1 and *[FeCp(dppe)(3-cq)][CF<sub>3</sub>SO<sub>3</sub>]*  
248 3

249 Prismatic crystals (0.1 x 0.1 x 0.2 mm and 0.2 x 0.1 x 0.1 mm respectively) were selected and mounted  
 250 on a MAR345 diffractometer with an image plate detector. Intensities were collected with graphite  
 251 monochromatized Mo Kα radiation. Lorentz polarization and absorption corrections were made. The  
 252 structures were solved by Direct methods, using SHELXS computer program [29] and refined by full-

253 matrix least-squares method with SHELX93 computer program [30], (very negative intensities were not  
254 assumed). The function minimized was  $\sum w||F_o|^2 - |F_c|^2|^2$ , where  $w = [\sigma^2(I) + (0.0566P)^2 + 0.4472P]^{-1}$ ,  
255 and  $P = (|F_o|^2 + 2|F_c|^2) / 3$ ,  $f$ ,  $f'$  and  $f''$  were taken from International Tables of X-Ray Crystallography  
256 [31]. All H atoms were located from a difference synthesis and refined with an overall isotropic  
257 temperature factor. CCDC 939633 and 939634 contain the supplementary crystallographic data for this  
258 paper. These data can be obtained free of charge from the Cambridge Crystallographic Data Centre via  
259 [www.ccdc.cam.ac.uk/data\\_request/cif](http://www.ccdc.cam.ac.uk/data_request/cif).

260

#### 261 2.4. Electrochemical experiments

262 The electrochemical experiments were performed on an EG&G Princeton Applied Research Model  
263 273A potentiostat/galvanostat and monitored with a personal computer loaded with Electrochemistry  
264 PowerSuite v2.51 software from Princeton Applied Research. Cyclic voltammograms were obtained in  
265 0.1 M or 0.2 M solutions of [NBu<sub>4</sub>][PF<sub>6</sub>] in CH<sub>3</sub>CN or CH<sub>2</sub>Cl<sub>2</sub> respectively, using a three-electrode  
266 configuration cell with a platinum-disk working electrode (1.0 mm diameter) probed by a Luggin  
267 capillary connected to a silver-wire pseudo-reference electrode and a Pt wire counter electrode. The  
268 electrochemical experiments were performed under a dinitrogen atmosphere at room temperature. The  
269 redox potentials were measured in the presence of ferrocene as the internal standard and the redox  
270 potential values are normally quoted relative to the SCE by using the ferrocenium/ferrocene redox  
271 couple ( $E_{1/2} = 0.46$  or  $0.40$  V vs. SCE for CH<sub>2</sub>Cl<sub>2</sub> or CH<sub>3</sub>CN, respectively) [32]. The supporting  
272 electrolyte was purchased from Fluka, electrochemical grade was dried under vacuum for several hours  
273 and used without further purification. Reagent grade acetonitrile and dichloromethane were dried over  
274 P<sub>2</sub>O<sub>5</sub> and CaH<sub>2</sub>, respectively, and distilled under dinitrogen atmosphere before use.

275

#### 276 2.5. DNA interaction studies

##### 277 2.5.1. Formation of drug-DNA complexes

278 Deionized Milli-Q water (18.2 M $\Omega$ ) was filtered through 0.2- $\mu$ m FP030/3 filters (Schleicher & Schuell)  
279 and centrifuged at 4.000 g prior to use. pBR322 DNA was heated at 60 °C for 10 min to obtain open  
280 circular (OC) form. To stock aqueous solutions of plasmid pBR322 DNA in Hepes buffer (4 mM Hepes,  
281 pH 7.4/2 mM MgCl<sub>2</sub>) were added aqueous solutions (with 4% of DMSO) of complexes 1-5 in a  
282 relationship DNA base pair to complex 10:1. In parallel experiments, blank sample of free DNA and  
283 DNA complex solutions were equilibrated at 37 °C for 4 h in the dark shortly thereafter.

284

##### 285 2.5.2. AFM imaging

286 Atomic force microscopy (AFM) samples were prepared by casting a 3- $\mu$ L drop of test solution onto  
287 freshly cleaved green mica disks as support. The drop was allowed to stand undisturbed for 3 min to  
288 favor the adsorbate-substrate interaction. Each DNA-laden disk was rinsed with Milli-Q water and was  
289 blown dry with clean compressed argon gas directed normal to the disk surface. Samples were stored  
290 over silica prior to AFM imaging. All AFM observations were made with a Nanoscope III Multimode  
291 AFM (Digital Instrumentals, Santa Barbara, CA). Nano-crystalline Si cantilevers of 125-nm length with  
292 a spring constant of 50 N/m average ended with conical-shaped Si probe tips of 10-nm apical radius and  
293 cone angle of 35° were used. High-resolution topographic AFM images were performed in air at room  
294 temperature (relative humidity < 40%) on different specimen areas of 2 x 2 mm operating in intermittent  
295 contact mode at a rate of 1-3 Hz.

296 2.6. *Growth inhibition assays*

297 Antiproliferative activity of these new iron complexes, and cisplatin, was tested in a cell culture system  
298 using the human acute promyelocytic leukemia cell line HL-60 (American Type Culture Collection  
299 (ATCC)). The cells were grown in RPMI-1640 medium supplemented with 10% (v/v) heat inactivated  
300 fetal bovine serum, 2 mmol/L glutamine (Invitrogen, Inc.) in a highly humidified atmosphere of 95%  
301 air with 5% CO<sub>2</sub> at 37 °C. Growth inhibitory effect was measured by the microculture tetrazolium [3-  
302 (4,5- dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide, MTT assay [33]. Cells were seeded at  
303 density 10<sup>4</sup> cells/well in 100 mL of culture medium and after that cells were treated with different  
304 concentrations ranging from 0 (culture medium) to 200 μM of compounds in 100 μl of culture medium.  
305 The exact concentrations assayed were 0.1, 0.24, 0.5, 0.75, 1, 2.5, 5, 10, 25, 50, 100 and 200 μM. All  
306 the assays were done in quadruplicate and three independent assays were realized. After incubation at  
307 37 °C during 24 h or 72 h, without washing, 20 μl of soluble tetrazolium salt was added to each well  
308 and incubated 3 additional hours. As we used soluble tetrazolium salts we determined the amount of  
309 formazan directly reading the absorbance at 490 nm in a spectrophotometric plate reader (Labsystems  
310 iEMS Reader MF). Cytotoxicity was evaluated in terms of cell growth inhibition in treated cultures  
311 versus that in untreated controls. IC<sub>50</sub>, the concentration of compound at which cell proliferation was  
312 50% of that observed in control cultures, were obtained by GraphPad Prism software, version 4.0.  
313 Experiments were repeated at least three times to get the mean values.

314

315

316 2.7. *Apoptosis assays*

317 Induction of apoptosis in vitro by iron compounds was determined by a flow cytometric assay with  
318 Annexin V-FITC by using an Annexin V-FITC Apoptosis Detection Kit (Roche) [34]. Exponentially  
319 growing HL-60 cells in 6-well plates (5 x 10<sup>5</sup> cells/well) were exposed to concentrations equal to the  
320 IC<sub>50</sub> of the platinum and iron drugs for 24 h. After, the cells were subjected to staining with the Annexin  
321 V-FITC and propidium iodide. The amount of apoptotic cells was analyzed by flow cytometry (BD  
322 FACSCalibur).

323

### 324 3. Results and discussion

325

#### 326 3.1. Synthesis of Fe(II) complexes

327 Five new cationic iron(II) complexes ( $\Gamma\epsilon 5$ ) of the general type  $[\text{Fe}(\eta^5\text{-C}_5\text{H}_5)(\text{dppe})\text{L}][\text{X}]$  where L = 2-  
 328 quinolinecarbonitrile (L1), 3-quinolinecarbonitrile (L2), 2-pyrazinecarbonitrile (L3) or 2,3-  
 329 pyrazinedicarbonitrile (L4) and X = PF<sub>6</sub> or CF<sub>3</sub>SO<sub>3</sub> were prepared by  $\sigma$  coordination of the functional  
 330 nitrile N $\equiv$ C group of the L1-L4 ligands (Scheme 1). Compounds were obtained in good yields (80-86%),  
 331 by halide abstraction from  $[\text{Fe}(\eta^5\text{-C}_5\text{H}_5)(\text{dppe})\text{I}]$  with thallium hexafluorophosphate or silver triflate, in  
 332 dichloromethane, in the presence of a slight excess of the adequate ligand and recrystallized from  
 333 dichloromethane/n-hexane solutions. The new compounds are stable in cellular media for several hours  
 334 (Fig. S1, in SI) and were all fully characterized by FT-IR, <sup>1</sup>H, <sup>13</sup>C and <sup>31</sup>P NMR spectroscopies; the  
 335 elemental analyses were in accordance with the proposed formulations. The structures of compounds 1  
 336 and 3 were also characterized by X-ray diffraction studies (see below).

337 Solid state FT-IR spectra (KBr pellets) of the complexes present the characteristic bands of the  
 338 cyclopentadienyl ligand ( $\approx 3050\text{ cm}^{-1}$ ), the PF<sub>6</sub> (840 and 550  $\text{cm}^{-1}$ ) or CF<sub>3</sub>SO<sub>3</sub> (1250  $\text{cm}^{-1}$ ) anion and  
 339 the characteristic stretching vibration of the nitrile functional group in the range 2200e2220  $\text{cm}^{-1}$ . The  
 340 coordination of the ligand to the metal center lead to a weakness of the  $\nu_{\text{N}\equiv\text{C}}$  of  $\sim 20\text{ cm}^{-1}$  for compounds  
 341 1-4 being this value somehow higher ( $-47\text{ cm}^{-1}$ ) for compound 5, probably due to the presence of the  
 342 second nitrile acceptor group. These negative shifts observed on  $\nu_{\text{N}\equiv\text{C}}$  are in good agreement with the  
 343 values found before for other related  $\eta^5$ -monocyclopentadieny iron compounds [35-37] and show an  
 344 enhanced  $\pi$ -backdonation from the metal *d* orbitals to the  $\pi^*$  orbital of the N $\equiv$ C group leading to a  
 345 decreased N $\equiv$ C bond order.

346 <sup>1</sup>H NMR chemical shifts of the cyclopentadienyl ring are displayed in the characteristic range of  
 347 monocationic iron(II) complexes (4.70-4.90 ppm, Table 1). The effect of coordination on the nitrile  
 348 ligands is observed through the shielding of the *ortho* protons relatively to N $\equiv$ C coordination position  
 349 ( $\approx 1.20$  ppm) in compounds 2-4 indicating an electronic flow towards the heteroaromatic ligand due to  
 350  $\pi$ -backdonation involving the metal center. Furthermore, an increased electronic density was also found  
 351 in compound 1 in both *ortho* ( $\approx 0.30$  ppm) and *meta* ( $\approx 1.20$  ppm) protons with special relevance for the  
 352 *meta* position (opposite to N in the heteroaromatic ring) probably due to a higher contribution of the  
 353 corresponding resonance form. The electronic flow in compound 1 is still observed in the second fused  
 354 ring ( $\approx 0.20$  ppm). This shielding effect on the second fused ring was also observed for compounds 2  
 355 and 3. Here, the difference in the anion did not cause any additional effect. Relatively to the  
 356 pyrazinecarbonitrile complexes (4 and 5) both protons suffered a shielding of about 0.30 ppm. <sup>13</sup>C NMR  
 357 data confirm the evidence found for proton spectra. The Cp ring chemical shifts are in the range usually  
 358 observed for Fe(II) cationic derivatives, a significant deshielding (up to  $\approx 14$  ppm) being observed on  
 359 the carbon of the N $\equiv$ C functional group upon coordination. All the other carbons of the chromophore  
 360 ligand were only slightly deshielded or remained almost unchanged for the studied compounds. <sup>31</sup>P  
 361 NMR data of the complexes showed the typical septuplet of the PF<sub>6</sub> anion at approximately - 144 ppm  
 362 (with the exception of compound 3 where the PF<sub>6</sub> anion was replaced by CF<sub>3</sub>SO<sub>3</sub>). Moreover, a single  
 363 sharp signal corresponding to the phosphine coligand ( $\approx 96$  ppm) was observed for all the complexes,  
 364 revealing the equivalency of the two phosphorus atoms, together with the expected deshielding upon  
 365 coordination, in accordance with its  $\sigma$  donor character. Table 1 displays the <sup>1</sup>H NMR chemical shifts of  
 366 the ligands (L1-L4) and corresponding complexes (1-5) in (CD<sub>3</sub>)<sub>2</sub>CO.

### 367 3.2. UV-Vis studies

368 The optical absorption spectra of these five new Fe(II) complexes and all the ligands were recorded in  
 369  $10^{-3}$ - $10^{-5}$ M dichloromethane solutions in order to identify any MLCT absorption and  $\pi$ - $\pi^*$  absorption  
 370 bands expected for these complexes (Table 2). The electronic spectra of all the compounds showed  
 371 intense absorption bands in the UV region, which can be assigned to electronic transitions occurring  
 372 both in the organometallic fragment  $\{\text{FeCp}(\text{dppe})\}^+$  ( $\lambda \approx 235$ - $260$  nm) and in the coordinated  
 373 chromophore ( $\lambda \approx 260$ - $450$  nm) (Fig. 1). Additional charge transfer (CT) bands were also observed in  
 374 all studied complexes. In fact, all complexes presented one band compatible with a MLCT nature, which  
 375 was confirmed by solvatochromism studies in DMSO (example given in Fig. 2 for complex 1).

376

### 377 3.3. X-ray structural studies of the complexes $[\text{Fe}(\eta^5\text{-C}_5\text{H}_5)(\text{dppe})(2\text{-cq})][\text{PF}_6]$ 1 and $[\text{Fe}(\eta^5\text{-}$ 378 $\text{C}_5\text{H}_5)(\text{dppe})(3\text{-cq})][\text{CF}_3\text{SO}_3]$ 3

379 Suitable crystals for X-ray diffraction studies of the complexes  $[\text{Fe}(\eta^5\text{-C}_5\text{H}_5)(\text{dppe})(2\text{-cq})][\text{PF}_6]$  1 and  
 380  $[\text{Fe}(\eta^5\text{-C}_5\text{H}_5)(\text{dppe})(3\text{-cq})][\text{CF}_3\text{SO}_3]$  3, crystallized in different crystalline systems and space groups  
 381 (monoclinic  $\text{P}2_1/\text{c}$  and monoclinic  $\text{P}2_1/\text{n}$  space groups, respectively). Crystal data and structure  
 382 refinement for both complexes are collected in Table 3. In Fig. 3 and Fig. 4 the molecular structure of  
 383 both complexes 1 and 3 are respectively presented. Both complexes present the usual distorted three-  
 384 legged piano stool geometry for  $\eta^5$ -monocyclopentadienyl complexes confirmed by P-Fe-P angles of  
 385  $86.93$  and  $87.11^\circ$  and N-Fe-P angles varying from  $90.02$  to  $92.64^\circ$ , with the remaining  $\eta^5$ -Cp(centroid)-Fe-  
 386 X (with X = N or P) angles between  $120.40$  and  $128.39^\circ$  (see Table 4). These values are within the range  
 387 found for  $\eta^5$ -monocyclopentadienylmetal nitrile derivatives with coordinated phosphanes. [38-40] The  
 388 distances Fe- $\eta^5$ -Cp(centroid) are very similar in both complexes ( $1.7153$  Å for complex 1, and  $1.7164$   
 389 Å for complex 3) and in good agreement with the donor/acceptor nature and number of other ligands  
 390 bound to iron atom. The distances Fe-N $\equiv$ C range from  $1.8670$  to  $1.8865$  Å are well within the values  
 391 expected for this family of compounds and their bond angles present only a slight deviation of the  
 392 linearity, with values in accordance to those found for related compounds [38-40]. Different spatial  
 393 orientation of the two isomeric ligands in both complexes can be observed. This fact can have some  
 394 biological importance since it might determine the way of interaction of each complex with DNA or  
 395 other biological molecules. In Table 4, the main bond lengths and angles are presented.

396

### 397 3.4. Electrochemical studies

398 In order to obtain an insight on the electron richness of the organometallic fragment and on the  
 399 coordinated ligands, the electrochemical properties of the ligands L1-L4 and the new iron(II) complexes  
 400 were studied by cyclic voltammetry in acetonitrile and dichloromethane solutions ( $1 \times 10^{-3}$  M) using  
 401  $0.1$  M or  $0.2$  M tetrabutylammonium hexafluorophosphate (TBAPF<sub>6</sub>) as supporting electrolyte, between  
 402 the limits imposed by the solvents. The electrochemical data measured for the studied compounds at the  
 403 scan rate of  $0.200$  V/s, are reported in Table 5 and Table 6. The redox behavior of the ligands L1-L3  
 404 was characterized by an irreversible reductive process near  $-1.70$  V, whereas for the 2,3-  
 405 pyrazinedicarbonitrile ligand (L4) this process is observed at  $\sim -1.15$  V, for both solvents. The  
 406 electrochemical responses of the iron(II) compounds 1, 2, 4 and 5 in acetonitrile were characterized by  
 407 the presence of an irreversible redox process in the positive potential range and two or three reductive  
 408 processes at negative potentials. This behavior is also expected for compound 3 since its cation is  
 409 isostructural of compound 2. The cyclic voltammogram of complex  $[\text{FeCp}(\text{dppe})(2,3\text{-dcpz})][\text{PF}_6]$  5 is

410 showed on Fig. 5 and typifies the behavior found for all the complexes in this solvent. The irreversible  
411 oxidation placed in the range 0.80e0.92 V can be attributed to the metal centered process ( $\text{Fe}^{\text{II}}/\text{Fe}^{\text{III}}$ ).  
412 The correspondent reductive wave was observed at 0.62 V for all the complexes and no changes in this  
413 potential were observed at different scan rates. This behavior can be related with an  $\text{Fe}^{\text{II}} \rightarrow \text{Fe}^{\text{III}}$   
414 oxidation, leading to the 17-electron species  $[\text{FeCp}(\text{dppe})(\text{L})]^{2+}$ , formed on the electrode surface which  
415 undergo fast substitution of the cyanoquinoline or pyrazine ligands by an acetonitrile molecule. The  
416 formed  $[\text{FeCp}(\text{dppe})(\text{NCCH}_3)]^+$  species is responsible for the observed reductive process when the scan  
417 direction is reverted. Moreover, the presence of a small reductive wave in the free ligand position ( $E_{\text{pc}}$   
418 = -0.16 V) (Fig. 5) confirms the ligand exchange process. This result is consistent with the redox behavior  
419 of the isolated complex  $[\text{FeCp}(\text{dppe})(\text{NCCH}_3)][\text{PF}_6]$  (Fig. 5) studied before in an independent  
420 experiment for related monocyclopentadienyliron(II)dppe derivatives [39] where the same  
421 electrochemical ligand exchange process was observed. In fact, for complexes  
422  $[\text{FeCp}(\text{dppe})(\text{NC}\{\text{SC}_4\text{H}_2\}_n\text{NO}_2)][\text{PF}_6]$ , the substitution of the thiophene ligands by the acetonitrile  
423 solvent was observed during the oxidative process in the electrochemical experiments. The reductive  
424 processes found at negative potentials were attributed to ligand-based processes occurring at the  
425 coordinated cyanoquinoline (L1 and L2) or pyrazine (L4) ligands, which became easier upon  
426 coordination.

427 The electrochemical response of compounds 1, 2 and 4 in dichloromethane is slightly different. Fig. 6  
428 shows the cyclic voltammogram of complex  $[\text{Fe}(\eta^5\text{-C}_5\text{H}_5)(\text{dppe})(3\text{-cq})][\text{PF}_6]$  2 which typifies the  
429 electrochemical behavior of complexes 1 and 2 with the cyanoquinoline ligands. No substitution  
430 processes involving solvent molecules were observed and the redox behavior is characterized by the  
431 presence of a single quasi-reversible process (I) attributed to the  $\text{Fe}^{\text{II}}/\text{Fe}^{\text{III}}$  redox pair in the range 0.84-  
432 0.90 V at positive potentials and one or two irreversible reductive waves at negative range (II and III,  
433 see Fig. 6) derived from processes occurring at the coordinated cyanoquinoline ligands. Nevertheless,  
434 for complex 4 a distinct behavior was observed and only an irreversible metal centered oxidation at 0.66  
435 V was observed, indicating a complete decomposition process for the complex after iron(II) oxidation.  
436 Moreover, the instability in the electrochemical cell of compound 5 did not allow further studies.

437

### 438 3.5.1. Atomic force microscopy

439 Compounds 1e5 were incubated for 4 h at 37 °C in the molar relationship compound:DNA = 1:2. The  
440 images obtained by AFM are presented in Fig. 7. These images show that all the compounds modify the  
441 free DNA forms. In Fig. 7(a) the free pBR322 plasmid DNA shows the usual open and supercoiled  
442 forms. The image (b) shows the modifications caused by compound 1 after incubation with pBR322  
443 DNA clearly showing broken chains and a strong interaction of the complex on DNA. In image (c) it  
444 can be mainly observed an aggregation of the forms on the mica surface and modifications in the  
445 supercoiling caused by interaction of compound 2 on pBR322 DNA. Compounds 3 and 4 produce similar  
446 effects on DNA (images (d) and (e), respectively): the number of supercoiled forms deposited on the  
447 mica has increased. Finally, image (f) reveals that complex 5 causes strong supercoiling in some DNA  
448 forms and kinks in those forms that remain open. The authors have observed similar effects in  
449 compounds with planar ligands which probably intercalate on DNA [41].

450

### 451 3.5.2. Cytotoxicity of the iron complexes against HL-60 cells

452 The cytotoxic effect of the iron complexes was examined on human leukemia cancer cells (HL-60) using  
453 the MTT assay, a colorimetric determination of cell viability during in vitro treatment with a drug. The  
454 assay, developed as an initial stage of drug screening, measures the amount of MTT reduction by

455 mitochondrial dehydrogenase and assumes that cell viability (corresponding to the reductive activity) is  
456 proportional to the production of purple formazan that is measured spectrophotometrically. A low IC<sub>50</sub>  
457 is desired and implies cytotoxicity or antiproliferation at low drug concentrations. All the new Fe(II)  
458 complexes were tested, together with cisplatin (CDDP) as a positive control. Cells were exposed to each  
459 compound continuously for a 24 h or a 72 h period of time and then assayed for growth using the MTT  
460 endpoint assay. Table 7 presents the IC<sub>50</sub> values against HL-60 cells. The IC<sub>50</sub> values at 24 h are lower  
461 than that for the reference drug, cisplatin. At 72 h, compounds 2 and 4 show higher IC<sub>50</sub> values than  
462 cisplatin, although compounds 1, 3 and 5 present an excellent antiproliferative behavior with IC<sub>50</sub> values  
463 lower than cisplatin forecasting interesting structureactivity relationships.

464

### 465 *3.6. Quantification of apoptosis by Annexin V binding and flow cytometry*

466 We have also analyzed, by Annexin V-PI flow cytometry, whether complexes 1-5 are able to induce  
467 apoptosis in HL-60 cells after 24 h of incubation at equitoxic concentrations (IC<sub>50</sub> values). Annexin V  
468 binds phosphatidyl serine residues, which are asymmetrically distributed towards the inner plasma  
469 membrane but migrate to the outer plasma membrane during apoptosis [33]. As it can be seen in Table  
470 8, complex 3 is able to induce apoptosis death in a 26.21%, close to that of cisplatin. Compounds 1, 4  
471 and 5, induce cell death by apoptosis in a lower percentage. Complex 2 presents only a discrete  
472 percentage of apoptosis at IC<sub>50</sub> dose, being the major death process caused by necrosis.

473

#### 474 4. Conclusions

475

476 A new family of five half sandwich compounds derived from “Fe<sup>II</sup>( $\eta^5$ -C<sub>5</sub>H<sub>5</sub>)” bearing a coordinated  
477 nitrile ligand, which structure comprises one or two N-heteroaromatic rings, has been synthesized and  
478 successfully characterized. Spectroscopic evidence shows a strong p-backdonation involving the metal  
479 center. X-ray studies for two of these new compounds revealed crystallization in the monoclinic P2<sub>1/c</sub>  
480 and monoclinic P2<sub>1/n</sub> space groups.

481 In a preliminary approach to evaluate the cytotoxic behavior of these new compounds against cancer  
482 cells, some studies were carried out involving human leukemia cancer cells (HL-60) by MTT assay.  
483 Also their interaction AFM images with pBR322 DNA plasmid show different behaviors that can be  
484 related with the NCL ligand. Indeed, IC<sub>50</sub> values together with the apoptosis results show significant  
485 differences between the whole series of compounds. There are some main conclusions that can be drawn:  
486 i) compound 1, bearing the 2-quinolinecarbonitrile, presents the best cytotoxicity and its AFM image  
487 showed the most relevant modifications in pBR322 DNA; ii) structural difference in the position of the  
488 nitrile group in compounds 1 and 2 (ortho vs. meta) leads to a decrease on the cytotoxicity (4-fold); iii)  
489 comparison of results of compounds 2 and 3 (bearing in both cases the 3-quinolinecarbonitrile ligand)  
490 shows that the replacement of PF<sub>6</sub> by CF<sub>3</sub>SO<sub>3</sub> leads to a more cytotoxicity compound and the principal  
491 mechanism of death is changed from necrosis to apoptosis; iv) 2-pyrazinecarbonitrile (L3) leads to the  
492 less cytotoxic compound (4); and finally v) the introduction of a second nitrile group in L3 leads to a 3-  
493 fold increase in the cytotoxic behavior (compound 5). The overall results show that after 24 h of  
494 incubation all the compounds are more cytotoxic than cisplatin. Thus, this is a potentially interesting  
495 family of compounds to be studied in the frame of anticancer drugs.

496

497 **ACKNOWLEDGEMENTS**

498

499 The authors thank financial support from the Portuguese Foundation for Science and Technology for  
500 the projects PEst-OE/QUI/UI0536/2011, PTDC/QUI-QUI/118077/2010, PTDC/QUI-  
501 QUI/101187/2008 and SFRH/BPD/80459/2011 (Andreia Valente's postdoctoral scholarship) and  
502 Spanish Ministry of Ciencia e Innovacion, projects CTQ2008-02064 and BIO2010-22321-C02-01.
