BACKGROUND AND AIMS: Despite the availability of new-generation drugs, hepatocellular carcinoma (HCC) is still the third most frequent cause of cancer-related deaths worldwide. Cerium oxide nanoparticles (CeO₂NPs) have emerged as an antioxidant agent in experimental liver disease because of their antioxidant, anti-inflammatory, and antisteatotic properties. In the present study, we aimed to elucidate the potential of CeO₂NPs as therapeutic agents in HCC.

APPROACH AND RESULTS: HCC was induced in 110 Wistar rats by intraperitoneal administration of diethylnitrosamine for 16 weeks. Animals were treated with vehicle or CeO₂NPs at weeks 16 and 17. At the eighteenth week, nanoceria biodistribution was assessed by mass spectrometry (MS). The effect of CeO₂NPs on tumor progression and animal survival was investigated. Hepatic tissue MS-based phosphoproteomics as well as analysis of principal lipid components were performed. The intracellular uptake of CeO₂NPs by human *ex vivo* perfused livers and human hepatocytes was analyzed. Nanoceria was mainly accumulated in the liver, where it reduced macrophage infiltration and inflammatory gene expression. Nanoceria treatment increased liver apoptotic activity, while proliferation was attenuated. Phosphoproteomic analysis revealed that CeO₂NPs affected the phosphorylation

of proteins mainly related to cell adhesion and RNA splicing. CeO₂NPs decreased phosphatidylcholine-derived arachidonic acid and reverted the HCC-induced increase of linoleic acid in several lipid components. Furthermore, CeO₂NPs reduced serum alpha-protein levels and improved the survival of HCC rats. Nanoceria uptake by *ex vivo* perfused human livers and *in vitro* human hepatocytes was also demonstrated.

CONCLUSIONS: These data indicate that CeO₂NPs partially revert the cellular mechanisms involved in tumor progression and significantly increase survival in HCC rats, suggesting that they could be effective in patients with HCC. (HEPATOLOGY 2020;72:1267-1282).

Hepatocellular carcinoma (HCC) is the third leading cause of death by cancer worldwide.⁽¹⁾ HCC commonly arises in patients with underlying chronic liver disease and is considered a typical inflammation-associated tumor.⁽²⁾ The appearance of cirrhosis greatly favors the onset of HCC through mechanisms not yet well known that began to be elucidated in recent years.⁽³⁾ In the last decade, complex

genetic alterations, epigenetic chromosomal aberrations, and cellular signaling pathways triggering tumor development, progression, and metastasis have been characterized.⁽⁴⁾ The current systemic treatments of HCC are based on molecularly targeted therapies. Sorafenib, a multikinase inhibitor, was the first compound for first-line treatment of patients with advanced-stage HCC.⁽⁵⁾ However, clinical trials have found only modest improvement in overall survival,⁽⁶⁾ and the emergence of resistance episodes reveals the need to develop effective therapies for HCC.⁽⁷⁾ Although the available drugs improve clinical outcomes, the median overall survival continues to be approximately 1 year.^(8,9)

Of particular importance is the role of reactive oxygen species (ROS) in the onset and progression of HCC.⁽¹⁰⁾ Mechanistic studies show that ROS induce alterations in DNA and modify key cellular processes such as cell proliferation and apoptosis.⁽¹¹⁾ Thus, it has been hypothesized that HCC develops because chronic oxidative stress exerts a selective pressure that favors the outgrowth of cells from progenitor clones that are more resistant to oxidative damage.⁽¹²⁾

Antioxidant agents have demonstrated their efficacy in chronic liver diseases equilibrating hepatic ROS metabolism, thereby improving liver functionality.⁽¹³⁾

Recently, cerium oxide nanoparticles (CeO₂NPs) have emerged as an antioxidant and anti-inflammatory agent. Superoxide dismutase activity⁽¹⁴⁾ (conversion of superoxide anion into hydrogen peroxide and finally oxygen), catalase activity^(15,16) (hydrogen peroxide into oxygen and water), and peroxidase activity⁽¹⁷⁾ (hydrogen peroxide into hydroxyl radicals), among others, have been attributed to CeO₂NPs. Consequently, the wide spectrum of antioxidant enzyme-mimetic activities of CeO₂NPs has been explored in the treatment of many diseases related to the overproduction of ROS. Thus, the ability of CeO₂NPs to modulate oxidative stress in diseases ranging from retinal degeneration,⁽¹⁸⁾ neurodegenerative diseases,⁽¹⁹⁾ diabetes,⁽²⁰⁾ ischemia,⁽²¹⁾ cardiopathies,⁽²²⁾ gastrointestinal inflammation,⁽²³⁾ and especially cancer has been described.⁽²⁴⁻²⁷⁾ As well, the therapeutic possibilities of CeO₂NPs have been shown in the case of experimental liver disease.⁽²⁸⁻³²⁾

We considered the potential therapeutic value of CeO₂NPs in an experimental model of HCC in rats by chronic administration of diethylnitrosamine (DEN). We assessed the impact of CeO₂NPs on tumor progression and survival, the accumulation in isolated human liver, and their intracellular adsorption by human liver-derived cancer cells.

Material and Methods

SYNTHESIS AND CHARACTERIZATION OF RAT SERUM ALBUMIN STABILIZED CeO₂NPs

CeO₂NPs of 4–5 nm were synthesized by the chemical precipitation of cerium (III) nitrate hexahydrate (Sigma-Aldrich, St. Louis, MO) in a basic aqueous solution.^(14,15,17,28) Cerium (III), 10 mM, was dissolved in 100 mL of Milli-Q water at room temperature. To this, 3 mL of tetramethylammonium hydroxide (TMAOH) solution (1 M) was added slowly at room temperature under vigorous stirring (final concentration of 10 mM), and the mixture was allowed to age under mild stirring overnight. During the first minutes, the solution is colorless, and then it turns progressively brownish. Afterward, nanoparticles (NPs) were purified by centrifugation (10,000g, 10 minutes, at room temperature), and the resultant pellet was resuspended in 100 mL aqueous solution of 1 mM TMAOH. The xlenol orange test and inductively coupled plasma-mass spectrometry (ICP-MS) indicated a full conversion of Ce to CeO₂NPs. Thus, the final CeO₂ concentration for this synthesis was determined to be 1.72 mg/mL (6.7•10¹⁵ NPs/mL) and then diluted to the 1 mg/mL employed solution. Further details on CeO₂NPs synthesis and characterization can be found in the Supporting Information.

CeO₂NPs ADMINISTRATION

CeO₂NPs or vehicle were dispersed in saline solution and intravenously given as a bolus (500 µL) through the tail vein. CeO₂NPs (0.1 mg/kg body weight) or vehicle (saline solution containing TMAOH ammonium salts 0.8 mM) were injected twice a week for 2 consecutive weeks starting at the sixteenth week after beginning DEN administration.

HCC INDUCTION IN RATS

Experimental studies were performed in 118 male Wistar rats weighing 200 g (Charles-River, Saint Aubin les Elseuf, France). HCC was chemically induced in 110 rats by an intraperitoneal administration of DEN (50 mg/kg body weight; Sigma-Aldrich) once a week for 16 weeks, and eight healthy rats were included as a control group.

ACCUMULATION OF Ce IN ISOLATED HUMAN LIVERS

To assess whether the human liver parallels the kinetic adsorption pattern shown by CeO₂NPs in the rat liver, human livers from three donors, designated subjects H1, H2, and H3, were used in the present study. Livers were procured in the Hospital Clinic (Barcelona, Spain), rejected for transplantation, and approved for research.

CeO₂NPs ADSORPTION BY HUMAN HEPATOCYTE CANCER CELLS

To investigate whether human hepatocytes are able to intracellularly take up CeO₂NPs, subsequent studies were performed in HepG2 cells, a human cell line derived from a liver HCC (ATCC, Manassas, VA).

ETHICAL APPROVAL

The study was approved and performed according to the criteria of the Investigation and Ethics Committee of the Hospital Clínic Universitari (Barcelona, Spain). Animals received humane care according to the criteria outlined in the “Guide for the Care and Use of Laboratory Animals”. The study of the human livers was conducted in the Hospital Clínic de Barcelona, which is part of the European Union-funded Consortium for Organ Preservation in Europe (<http://www.ope-eu.com>).

Results

CHARACTERIZATION OF CeO₂NPs

A description of the characterization of the CeO₂NPs used in this study has been published.⁽³²⁾ High-resolution transmission electron microscopic

(TEM) analysis indicated that the NPs had a spherical morphology and were predominantly within the size range of 4–20 nm. The X-ray diffraction pattern showed pure CeO₂NPs with the typical peak broadening characteristic of nanosized particles. Initially, the employed NPs are positively charged, and the colloidal stability is mediated by electrostatic repulsion (zeta potential +43.0 ± 1.3 mV, conductivity 0.303 ± 0.006 mS/cm, and pH 4.3). Albumin conjugation in the surface of the CeO₂NPs has been characterized by the increase in dynamic light scattering (from 5 to 20 nm) and decrease in zeta potential (from +42.8 to -10 mV, which is the average zeta potential value of proteins in serum) (Supporting Fig. S1). Indeed, the solubility of CeO₂NPs in physiological media is challenging, and a strong tendency to aggregate and sediment impedes their medical use even more, modifying their protective effects toward the proinflammatory (<https://www.frontiersin.org/articles/10.3389/fimmu.2017.00970/full>). To evaluate the electronic structure of the CeO₂NPs and the influence on Ce valence state due to the presence of rat serum albumin, we performed X-ray photoelectron spectroscopy measurements. Ce three-dimensional spectra of all samples are shown in Supporting Fig. S2, where it can be clearly observed that the Ce³⁺/Ce⁴⁺ ratio is not affected by the presence of bovine serum albumin in the CeO₂NPs surface.

THE RAT MODEL OF DEN-INDUCED LIVER INJURY EXHIBITS CHARACTERISTICS OF MULTIFOCAL HCC

Macroscopic examination of the liver specimens and histological examination confirmed the development of multifocal HCC nodules with a dysmorphic or dyschromic appearance (Fig. 1A) that was markedly attenuated in the animals receiving CeO₂NPs. Interestingly, DEN-injured rats treated with CeO₂NPs showed a significantly lower liver/body weight ratio (Fig. 1B).

LIVER AND SPLEEN ARE THE MAJOR TARGETS OF CeO₂NPs IN HCC RATS

Following intravenous CeO₂NPs administration, tissue Ce accumulation was analyzed by ICP-MS. Two weeks after the last administration of CeO₂NPs 90.0% and 7.7% of the total dose of Ce collected was located

in the liver and the spleen, respectively, whereas these figures were 77.3% and 21.7% 3 weeks after the completion of the CeO₂NPs dosing schedule (Fig. 1C).

SERUM BIOCHEMICAL PARAMETERS AND CIRCULATING LEVELS OF ALPHA-FETOPROTEIN

HCC rats showed significant alterations of liver function tests such as decreased levels of albumin and glucose, higher levels of total bilirubin and total cholesterol, and increased activity of markers of hepatocyte injury such as aspartate aminotransferase, alanine aminotransferase, and gamma-glutamyl transferase. We did not observe significant differences between HCC rats receiving or not receiving CeO₂NPs (Supporting Table S2). However, nanoceria administration did significantly reduce the circulating levels of alpha-fetoprotein (AFP), a tumor-associated marker for HCC (Fig. 1B).

EFFECT OF CeO₂NPs ON COLLAGEN CONTENT AND CELLULAR APOPTOSIS IN LIVER TISSUE

Long-term administration of DEN promoted incipient formation of fibrotic septa and periportal accumulation of collagen as a consequence of continuous hepatic injury. However, no significant differences in hepatic collagen content were noted between treated and nontreated rats with HCC (Fig. 2A).

The terminal deoxynucleotidyl transferase-mediated deoxyuridine triphosphate nick-end labeling (TUNEL) assay showed a significant increase in positive cells in the liver sections of DEN-injured rats treated with CeO₂NPs (Fig. 2B). We also observed a significantly increased protein expression of activated caspase-3 in HCC rats treated with CeO₂NPs (Fig. 2C). These results indicate that treatment with CeO₂NPs results in acceleration of apoptosis, thereby inhibiting HCC growth.

CeO₂NPs DECREASE MACROPHAGE INFILTRATION AND REDUCE INFLAMMATORY GENE OVEREXPRESSION IN LIVER TISSUE

Macrophage infiltration measured by positive cluster of differentiation 68 (CD68) staining was

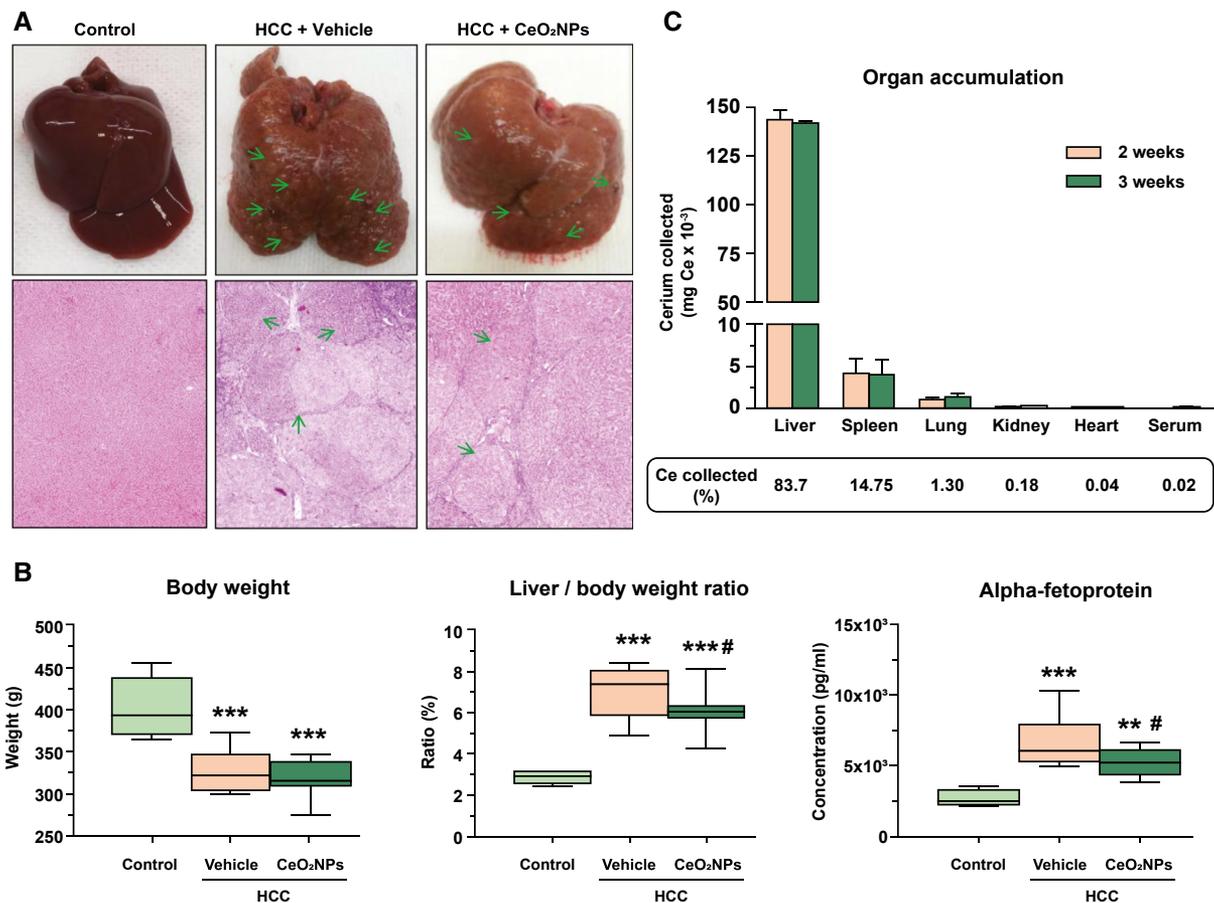

FIG. 1. DEN-induced model of HCC and biodistribution of CeO₂NPs. (A) Representative photographs of the liver and hematoxylin and eosin staining (magnification, 40) from control and DEN-injured rats. DEN was administered for 16 weeks, followed by a 2-week washout period. Green arrows point at nodules present in HCC rats. (B) Body weight, liver/body weight ratio, and serum levels of AFP in control rats and HCC rats. Serum samples were collected 1 week after the last dose of CeO₂NPs. (C) ICP-MS quantification of cerium. Major organs and serum from HCC rats receiving CeO₂NPs collected at two different time points: 2 (n = 3) and 3 (n = 4) weeks after the last administration of CeO₂NPs. This corresponds to the nineteenth and twentieth weeks after starting DEN administration. ***P* < 0.01 and ****P* < 0.001 versus control; #*P* < 0.05 versus HCC + vehicle. One-way analysis of variance and Newman-Keuls *post hoc* test.

observed in intratumoral and peritumoral areas, being significantly lower in HCC rats receiving CeO₂NPs (Fig. 3A). mRNA expression of inflammatory, macrophage phenotype, cell growth and differentiation genes was analyzed in liver biopsies of control and HCC rats. Chronic administration of DEN induced higher gene expression of macrophage M1 markers, such as interleukin 1 beta, tumor necrosis factor alpha, inducible nitric oxide synthase, and cyclooxygenase-2 (Supporting Table S3). Interestingly, administration of CeO₂NPs significantly down-regulated M1 genes involved in proinflammatory function.

CeO₂NPs DECREASE HEPATIC CELLULAR PROLIFERATION

We assessed the effect of CeO₂NPs on cell proliferation and the phosphorylation levels of proteins involved in tumor progression. Immunohistochemistry revealed abundant cellular proliferation in liver sections from DEN-injured animals. The cell proliferation rate, measured as the percent of Ki67-positive hepatocyte nuclei, was markedly lower in CeO₂NPs-treated rats (Fig. 3B). To ascertain the potential effect of CeO₂NPs on interfering with the Ras/mitogen-activated protein kinase (MAPK) signaling pathway,

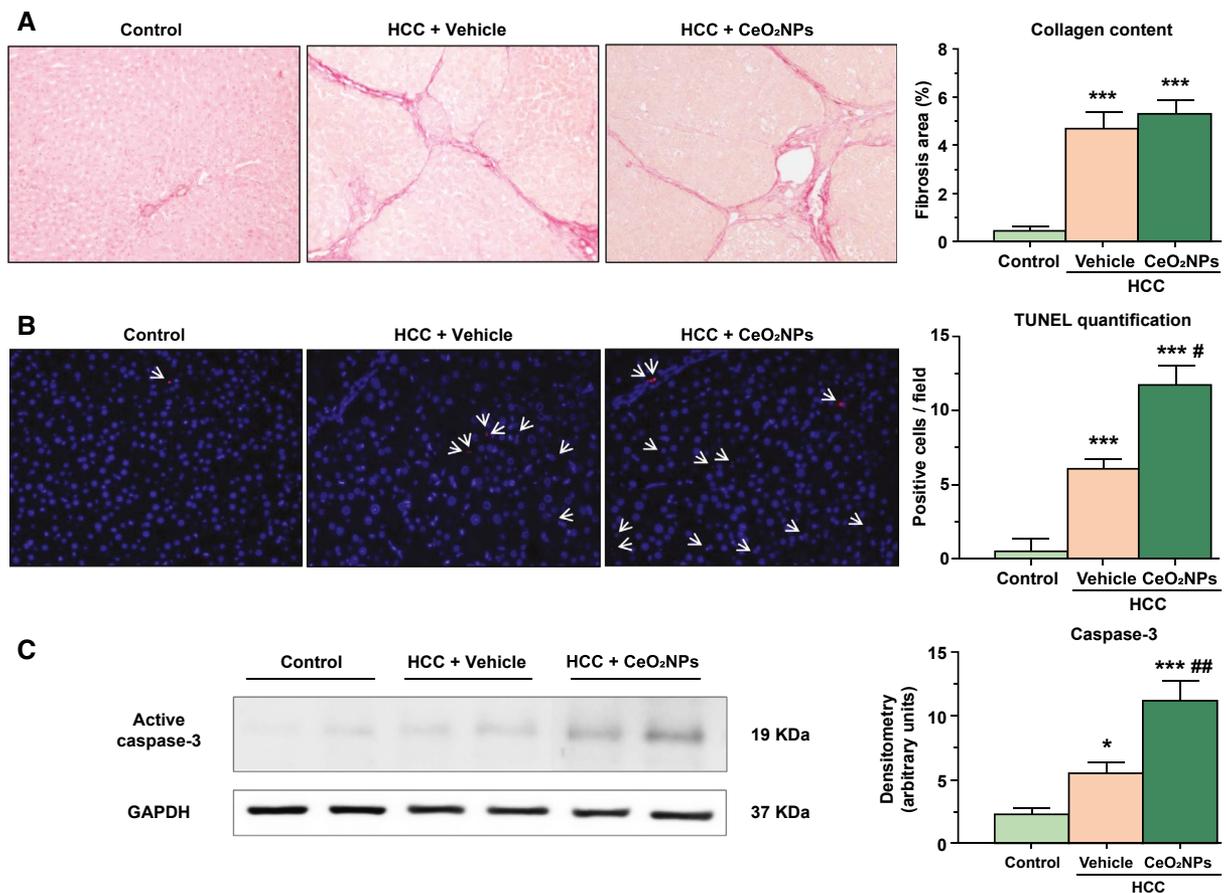

FIG. 2. Effect of CeO₂NPs on hepatic fibrosis and cellular apoptosis. (A) Sirius red staining of representative liver sections obtained from control and DEN-injured rats (magnification, 100). (B) Representative TUNEL assay in liver sections of control rats and HCC rats (magnification, 200). White arrows point to apoptotic (red) cells. (C) Representative western blot for activated caspase-3 in liver tissue of control rats and HCC rats. **P* < 0.05 and ****P* < 0.001 versus control group; #*P* < 0.05 and ##*P* < 0.01 versus HCC + vehicle. One-way analysis of variance and Newman-Keuls *post hoc* test, Kruskal-Wallis test, and Dunn's *post hoc* test, with unpaired Student *t* test when appropriate. Abbreviation: GAPDH, glyceraldehyde 3-phosphate dehydrogenase.

we assessed protein expression of total extracellular signal-regulated kinase 1/2 (ERK1/2) and phosphorylated ERK1/2 (P-ERK1/2) in liver samples of HCC rats by western blot. It was of note that CeO₂NPs treatment resulted in a significant reduction of P-ERK1/2 (Fig. 3C). These results suggest that the antiproliferative action of CeO₂NPs is related to interference with the Ras/MAPK signaling pathway in HCC rats.

EFFECT OF CeO₂NPs ON ALTERED CELL SIGNALING PATHWAYS IN LIVER TISSUE

To investigate the effects of CeO₂NPs on kinase-driven signaling pathways, we evaluated the

phosphoproteome profile by mass spectrometry (MS). We identified and quantified a total of 5,048 phosphopeptides in six independent biological replicates that were run twice. Principal component analysis showed that CeO₂NPs-treated samples separate from vehicle-treated samples in principal component 1 (Fig. 4A). At arbitrary threshold values of ±0.8-fold change (log₂) and *P* < 0.05, the phosphorylation of 349 peptides was increased, while the phosphorylation of 133 was decreased after CeO₂NPs treatment (Fig. 4B; Supporting Table S4). This set of regulated phosphopeptides included 20 phosphorylation sites in kinases, of which 11 were increased and nine were decreased (Fig. 4C). Gene ontology analysis showed that cell-cell adhesion and RNA splicing were enriched in the set of genes

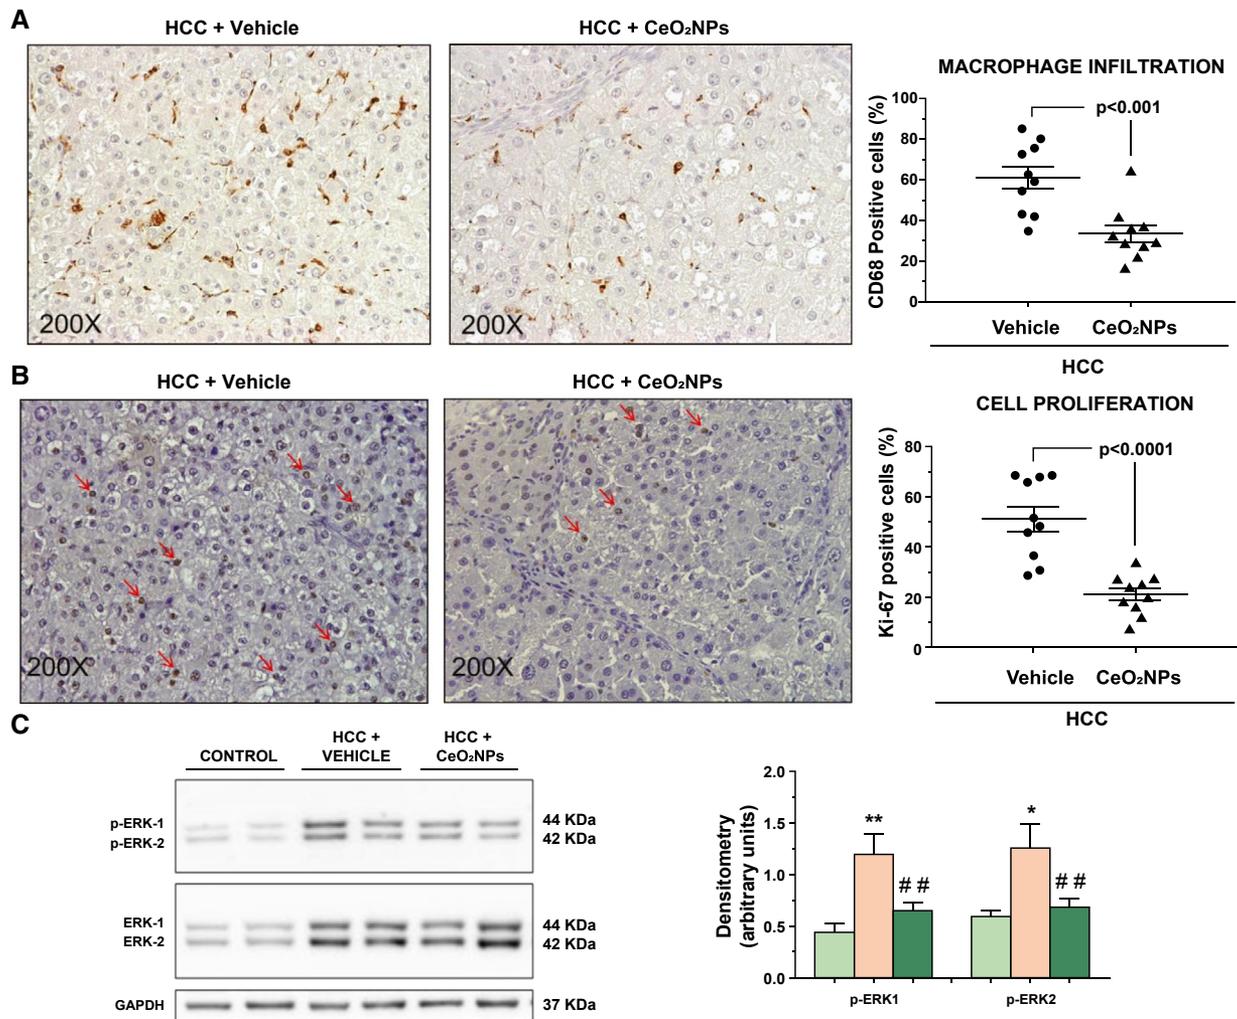

FIG. 3. Effect of CeO₂NPs on infiltrating cells, cellular proliferation, and levels of P-ERK1/2 in tumoral tissue. (A) CD68 immunostaining of representative liver sections from HCC rats (magnification, 200). (B) Ki67 immunostaining of representative liver sections from HCC rats (magnification, 200). Red arrows mark nuclei positive for Ki67 staining. (C) Representative western blots of total ERK1/2 and P-ERK1/2 in liver homogenates of control rats and HCC rats. Forty micrograms of protein extracts were loaded per lane. * $P < 0.05$ and ** $P < 0.01$ versus control; ## $P < 0.01$ versus HCC + vehicle. One-way analysis of variance and Newman-Keuls *post hoc* test, with unpaired Student *t* test when appropriate. Abbreviation: GAPDH, glyceraldehyde 3-phosphate dehydrogenase.

that code for the regulated phosphopeptides (Fig. 4D). The set of regulated phosphopeptides linked to cell–cell adhesion included 43 sites in 27 proteins that presented an increased phosphorylation after CeO₂NPs treatment and 16 sites in 11 proteins that presented a decreased phosphorylation after NP treatment (Fig. 4E). In addition, proteins linked to cell–matrix adhesion including CD44 and integrin beta 4 (Itgb4) showed a decreased phosphorylation

after CeO₂NPs treatment (Fig. 4F). Finally, the set of regulated phosphopeptides linked to RNA splicing included 36 sites in 18 proteins that presented increased phosphorylation and four sites in three proteins that showed decreased phosphorylation (Fig. 4G). These data suggest that CeO₂NPs have a global effect on the phosphorylation pattern of liver cells from rats with HCC that mainly affects proteins related to cell adhesion and RNA splicing.

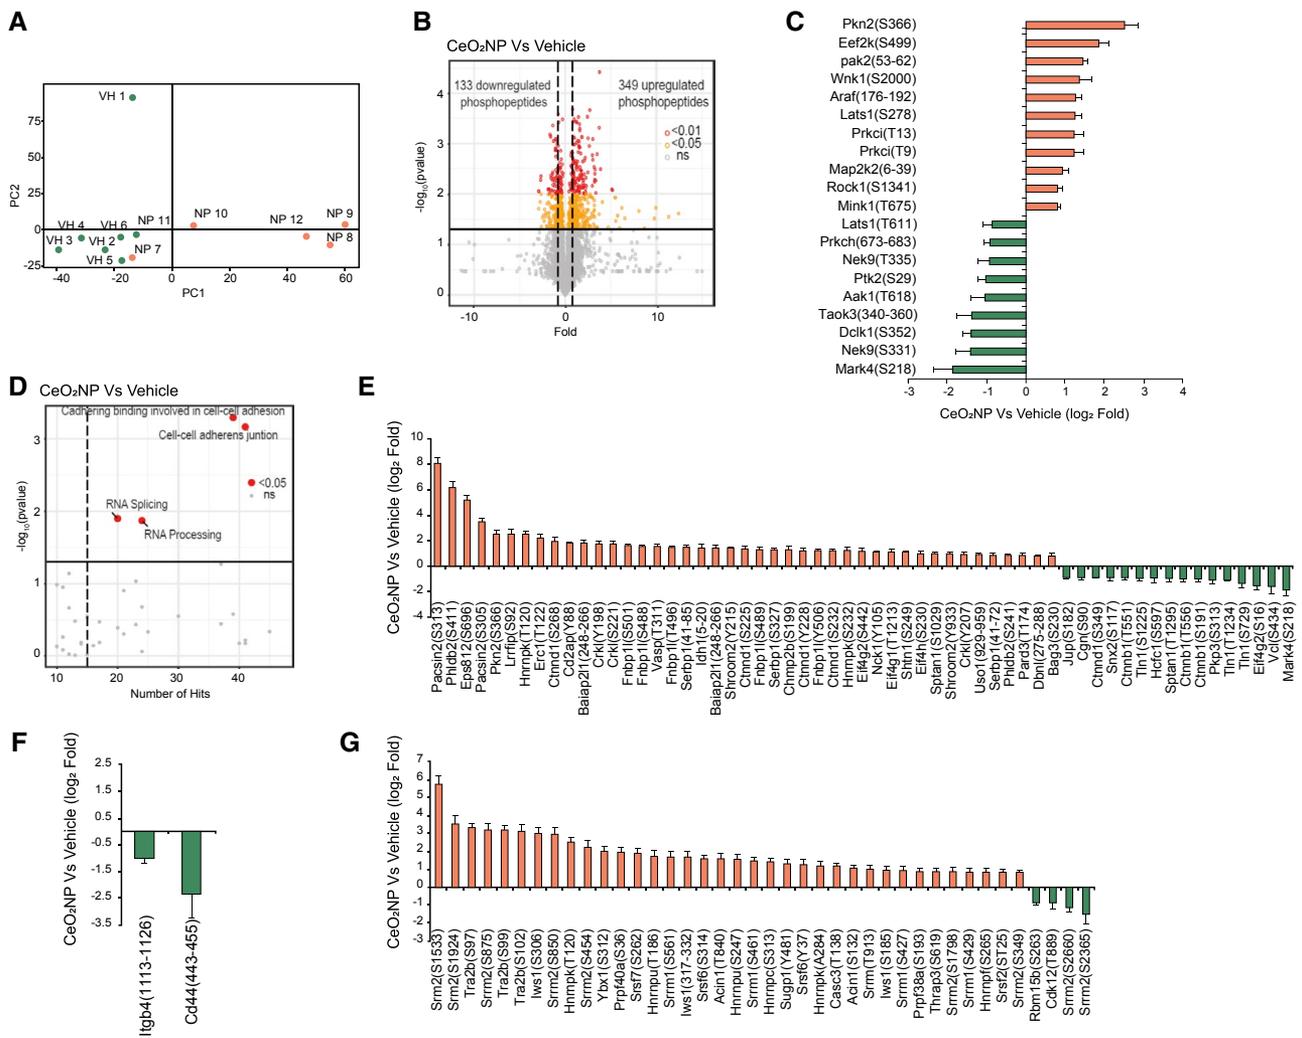

FIG. 4. Effect of CeO₂NPs on the phosphoproteome of livers from rats with HCC. (A) Principal component analysis showing the global effect of CeO₂NPs on the phosphoproteome of hepatic cells from HCC rats. Blue dots (VH) indicate biological replicates treated with vehicle, while red dots (NP) indicate replicates treated with CeO₂NPs. (B) Volcano plot showing phosphopeptides regulated by CeO₂NPs. Peptides were considered regulated when $P < 0.05$ (1.3 in $-\log_{10}$ scale) and fold change in \log_2 scale >0.8 (increased) or <-0.8 (decreased). Statistical significance was assessed using an unpaired two-tailed Student t test. (C) Chart showing phosphorylation sites in kinases regulated by CeO₂NPs treatment. (D) Volcano plot showing gene ontologies enriched in proteins whose phosphorylation was regulated by CeO₂NPs. Statistical significance of the enrichment was assessed using a modified Fisher's exact test. (E) Phosphorylation sites linked to cell–cell adhesion and regulated by CeO₂NPs treatment. (F) Effect of CeO₂NPs treatment over the phosphorylation of CD44 and Itgb4. (G) Phosphorylation sites linked to RNA splicing and regulated by CeO₂NPs treatment.

EFFECT OF CeO₂NPs ON HEPATIC LIPID METABOLISM

Analysis of total fatty acids (FAs) of principal lipid components in hepatic tissue of HCC animals indicates a dysregulation of FA metabolism mainly occurring in cholesterol ester (CE)– and nonesterified FA (NEFA)– derived FAs (Supporting Table S5). The most important effects induced by CeO₂NPs were found in

phosphatidylcholine (PC)–derived FAs, which are by far the most abundant lipid component in the liver. In fact, we observed a significant decrease in polyunsaturated FAs (PUFAs), which was exclusively due to a marked diminution in arachidonic acid (AA; C20:4n6; Fig. 5A). We also observed significant changes in C14:0, C16:1, and C17:0, although the differences were quantitatively much less important. Moreover, in NEFA-derived, triglyceride (TG)–derived, and CE-derived FAs, we

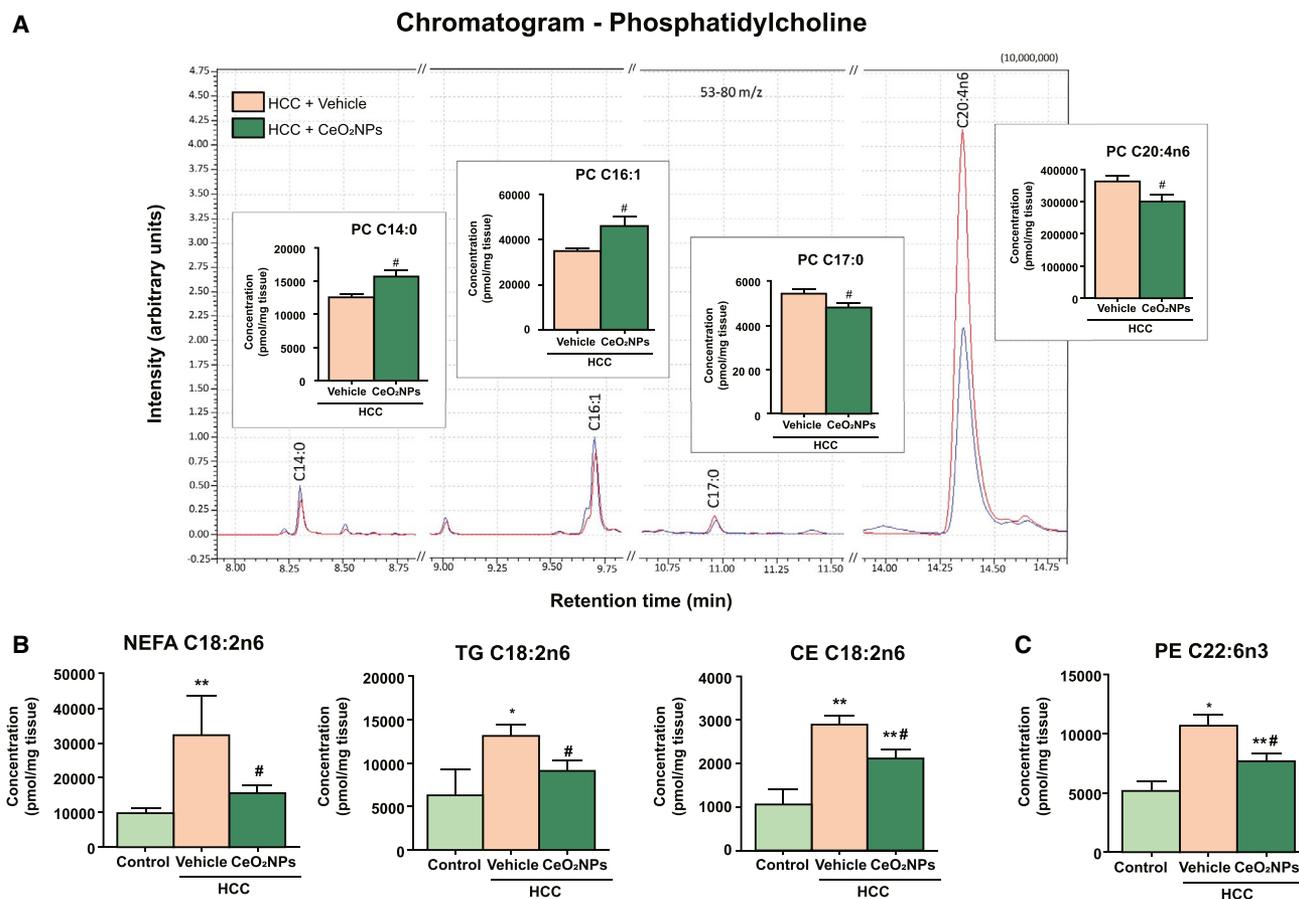

FIG. 5. Representative chromatogram of PC-derived FAs in rats with HCC. (A) Superposition of a representative gas chromatography MS total ion current chromatograms showing the analysis of PC-derived FAs obtained from HCC rats treated with vehicle (red) or CeO₂NPs (blue). The represented peaks are the FAs which showed significant differences between groups. Gas chromatography peaks are labeled with the corresponding FA identification. For each peak there is a graph with the quantification of the FA. (B) Effect of nanoceria treatment in linoleic FAs in different lipid components (NEFA, TG, and CE). (C) Effect of CeO₂NPs in PE-derived docosahexaenoic acid (C22:6n3). * $P < 0.05$ and ** $P < 0.01$ versus control; # $P < 0.05$ versus HCC + vehicle. Unpaired Student t test and Mann-Whitney test when appropriate.

observed that HCC rats showed significantly increased liver content of linoleic acid (LA; C18:2n6) than healthy rats, a phenomenon that was reversed in HCC animals treated with CeO₂NPs (Fig. 5B). Of note, on analyzing phosphatidylethanolamine (PE)-derived FAs, we observed that CeO₂NPs administration was associated with a significant reduction in the very long chain PUFA docosahexaenoic acid (C22:6n3) (Fig. 5C).

CeO₂NPs IMPROVE SURVIVAL IN DEN-INJURED RATS

To assess how the above changes translate into clinical outcome, we investigated the impact of these

NPs on the survival of two groups of HCC rats. The median survival reached by CeO₂NPs-treated rats was significantly higher than that in rats receiving vehicle ($P < 0.05$) (Fig. 6A). Next, we were interested in comparing the effect of CeO₂NPs to that of sorafenib. Four groups of rats receiving vehicle, CeO₂NPs, sorafenib, and CeO₂NPs plus sorafenib were investigated. The median survival was markedly lower in HCC rats receiving vehicle (15.5 days, $P < 0.05$) than in those animals receiving CeO₂NPs (31 days), sorafenib (33.5 days), or CeO₂NPs plus sorafenib (33.5 days) (Fig. 6B). The combined therapy showed the longest survival, although differences did not reach statistical significance.

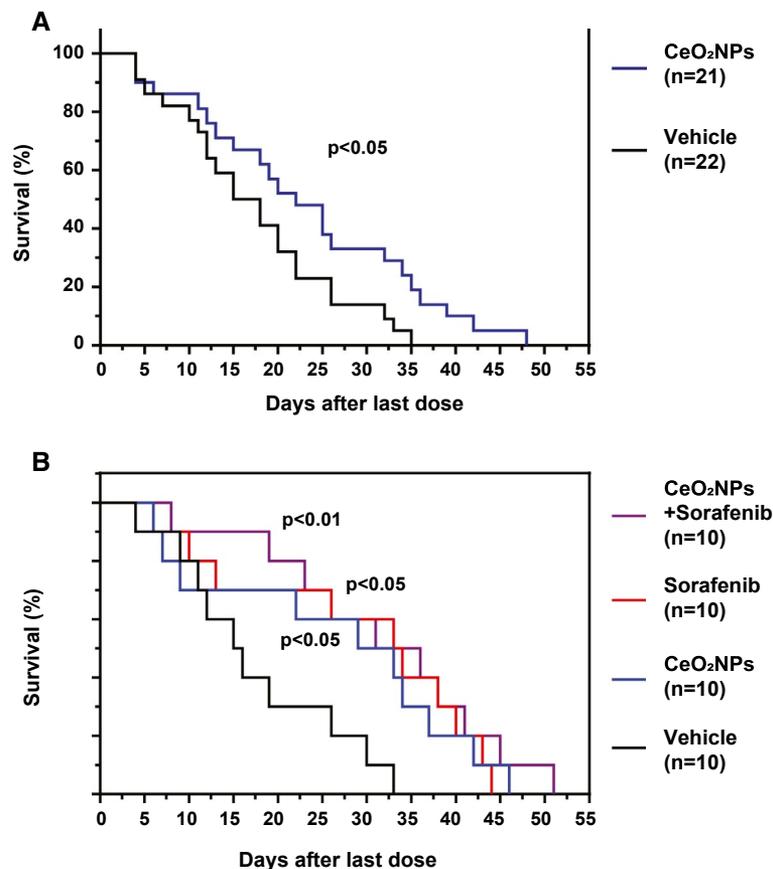

FIG. 6. Effect of CeO₂NPs on survival. (A) HCC rats randomly received two weekly doses of CeO₂NPs or vehicle through the tail vein at the sixteenth and seventeenth weeks, and their survival was analyzed. (B) HCC rats were randomly distributed into four groups receiving vehicle, CeO₂NPs, sorafenib, or the combination CeO₂NPs and sorafenib. Sorafenib was delivered daily by intragastric administration (10 mg/kg) for 14 days. $P < 0.05$ and $P < 0.01$ versus HCC + vehicle, log-rank (Mantel-Cox) test.

CeO₂NPs RETENTION BY HUMAN LIVER

To determine whether CeO₂NPs can be internalized by the human liver, three experimentally viable human livers, declined for transplantation, were perfused with CeO₂NPs under normothermic machine perfusion (NMP) (Supporting Information). Liver function tests and hemodynamic parameters were monitored during perfusion (data not shown) to ensure organ viability and proper device functioning.

To study the cellular uptake and intracellular localization of CeO₂NPs in human livers, ICP-MS and TEM imaging were performed. The concentration of Ce in the serum leaving the liver through the hepatic veins reached the highest levels 15 minutes after NPs administration (Fig. 7A). At 30 minutes of perfusion, the amount of Ce in the perfusate was reduced by at

least 50% when compared to the previous time point and further decreased at 60 minutes. In the case of donor H3, at 60 minutes of NMP, the Ce concentration in the perfusate was still around 45% due to the fact that in this particular organ the injected dose of NPs was almost 100 times higher than in H1 and H2 livers.

Ce subcellular location was examined using conventional bright and enhanced dark field TEM. Liver tissue from all donors was morphologically well preserved, and the cells presented a viable morphology. Liver biopsies obtained from donor H3 were examined under conventional TEM and energy-dispersive X-ray spectroscopy (EDX). In conventional TEM, CeO₂NPs appeared as small, dense, black structures in the form of agglomerates of different sizes inside blood vessels, the space of Disse, endothelial cells, and some blood circulating cells (Fig. 7B). CeO₂NPs

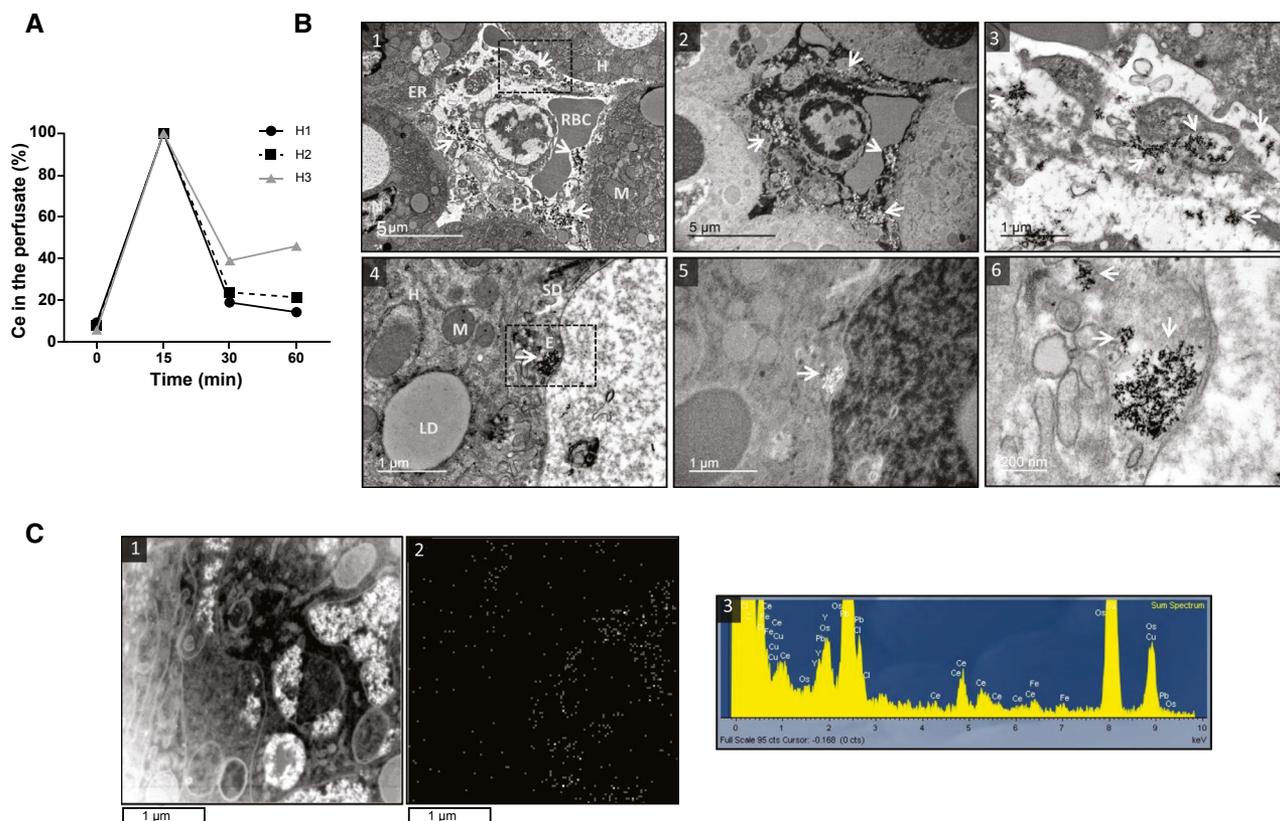

FIG. 7. Accumulation of Ce in isolated human livers. (A) Amount of Ce in the perfusate 0, 15, 30, and 60 minutes after NP administration. ICP-MS data are expressed as percent of Ce present in the perfusate compared to the highest Ce amount present in the serum of each liver. (B) Assessment of CeO_2 NPs subcellular location in human hepatic tissue after 1 hour of NP infusion; (1,2,3) TEM image of a blood vessel containing NPs surrounded by hepatocytes. In bright field (1), aggregates of CeO_2 NPs (white arrows) appear as dark, electron-dense spots. In dark field (2), nanoparticles are seen bright. (3) Magnified view of the boxed area depicting the nanoparticles in the space of Disse. (4,5) TEM image of a hepatocyte in the proximity of an endothelial cell containing CeO_2 NPs, bright and dark field, respectively. (6) High-magnification micrograph of the boxed area showing in detail the NPs inside the endothelial cell. *Apoptotic cell. (C) (1) STEM-HAADF image of endosome-like vesicles of an endothelial cell. (2) STEM-EDX element-distribution map showing the spatial distribution of Ce in the region outlined. Four adjacent pixel/spectra binned for each point. (3) EDX sum spectrum ($Y = \text{counts}$, $X = \text{keV}$) showing the average elemental composition of the image. Abbreviations: E, endothelial cell; ER, endoplasmic reticulum; H, hepatocyte; LD, lipid droplet; M, mitochondria; N, nucleus; P, platelet; RBC, red blood cell; S, sinusoid; SD, space of Disse.

were observed both free and within intracellular, single-membrane, endosome-like organelles. In dark field TEM, given its high atomic number relative to the elements typically found in organic tissues, Ce is expected to appear as very bright dots, as shown in Fig. 7B. The presence of Ce was further confirmed using high-angle annular dark-field scanning transmission electron microscopy (HAADF-STEM), which provides structural and chemical information with atomic resolution. Figure 7C shows a representative region in the set of analyzed images. The elemental map (central panel) shows the spatial distribution of Ce in the region outlined in the left panel, and the

EDX spectrum (right panel) confirms the elemental composition. In addition to Os from the postfixation, Cu from the TEM grid, and Pb from the staining, Ce is the only element detected by using EDX analysis.

CeO_2 NPs ADSORPTION BY HUMAN HEPATOCYTE CANCER CELLS

To assess whether human hepatocytes can internalize CeO_2 NPs, HepG2 cells, a human derived cell cancer line, were exposed to CeO_2 NPs (10 $\mu\text{g}/\text{mL}$) for 24 hours and subjected to TEM analysis. NPs were

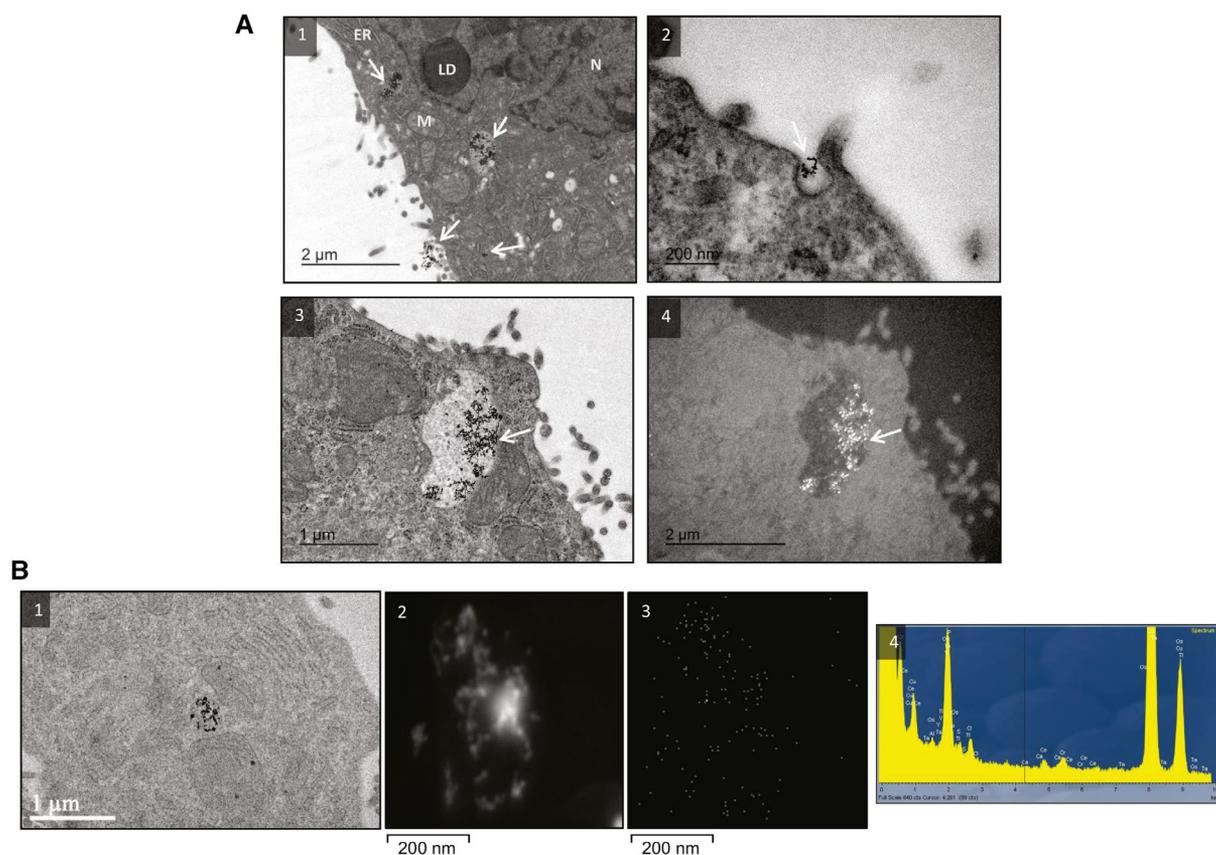

FIG. 8. CeO₂NPs adsorption in human hepatocyte cancer cells. (A) TEMs of HepG2 cells showing the uptake of NPs: (1) hepatocyte exposed to CeO₂NPs (white arrows) for 24 hours, with some NPs adhering to the cell membrane, others confined to vesicles, and a few free in the cytoplasm; (2) formation of pseudopodia with NPs in the center; (3,4) vesicle loaded with CeO₂NPs in bright and dark fields, respectively. (B) (1) TEM image displaying NPs in the cytoplasm of a hepatocyte; (2) STEM-HAADF image from the NPs; (3) Ce elemental mapping with four adjacent pixel/spectra binned for each point; (4) EDX sum spectrum (Y = counts, X = keV) showing the average elemental composition of the image. Abbreviations: ER, endoplasmic reticulum; LD, lipid droplet; M, mitochondria; N, nucleus.

strongly attached to the outer leaflet of the plasmatic membrane, free in the cytoplasm, and mostly inside numerous endosome-like bodies of diverse morphology (Fig. 8A). The mitochondria, the endoplasmic reticulum, and the nucleus of these hepatocytes appeared normal. To verify that the electron-dense granules were indeed CeO₂NPs, we performed dark field microscopy followed by HAADF-STEM. In both dark field TEM and STEM, NPs appeared as bright spots. The Ce elemental map and EDX spectrum confirmed the presence of Ce in the preparations (Fig. 8B).

Discussion

The ability of nanocerium to catalyze redox reactions has been widely used in petrochemical

industries and catalytic exhaust converters for decades.⁽³³⁾ The use of these NPs as a therapeutic tool is still a matter of concern. This is mainly due to the tendency of CeO₂NPs to evolve when in contact with physiological media.⁽³⁴⁾ Variability in the response and loss of antioxidant activity are the outcomes of these alterations. In the current investigation, some of these difficulties have been overcome by preparing albumin-coated CeO₂NPs with high monodispersity and high stability in the physiological media. This coating prevents the development of large NP aggregates and protein corona formation, resulting in a stable colloidal solution with sustained and more intense effects.

Unfortunately, HCC is still rather orphan in terms of highly effective systemic treatment. In this context, oxidative stress, mainly contributed by ROS, has

been implicated in the pathogenesis of several diseases including cancer. It is well known that ROS can drive the initial development and progression of cancer as well as down-regulate antioxidant enzymes that normally combat free radical production.⁽¹⁰⁾ Consequently, many antioxidant compounds, enzymes, and inhibitors of reduced nicotinamide adenine dinucleotide phosphate oxidase have been studied for treating chronic inflammation and cancer. However, results to date have been suboptimal, mainly due to their low systemic bioavailability and insufficient levels at the target sites.

Here we consider that CeO₂NPs could be an NP-based therapy platform in HCC, which would be able to induce ROS degradation and tumor recession by virtue of their great self-regenerating antioxidant capacity. Because the antioxidant effect of CeO₂NPs is catalytic and consequently permanent, this would represent a clear competitive advantage over other antioxidant therapies needing permanent application. In addition, CeO₂NPs are only active as a catalyst when there is an excess of ROS; otherwise, they are inert and appear innocuous.

The carcinogenic effect of DEN is due to an enhancement of hepatocyte proliferation mainly in the centrilobular hepatocytes. DEN is bioactivated following hydroxylation by the cytochrome P450 (CYP) system; then, the hydroxylated DEN is oxidized by CYP2E1 to reactive products in rat liver liposomes. DEN-treated rats displayed macroscopically distorted liver, with altered liver weight and anomalous microscopic architecture of the liver parenchyma showing diffuse dysplasia and fibrotic tracts. This prompted us to assess whether the HCC liver, as indeed occurs in the normal liver, is also a main target for CeO₂NPs. Our results further confirm that, even in a liver with intense tumorigenic activity, CeO₂NPs maintain their high selective targeting on the hepatic tissue.

Parameters indicating altered tissue growth or proliferation and ongoing proinflammatory processes were significantly less activated in rats receiving CeO₂NPs. Treated rats showed increased liver/body weight ratio, decreased macrophage infiltration, and lower amount of Ki67-positive cells. Ki67 is a nuclear antigen extensively used as a proliferation marker and as a prognostic indicator for cancer. We also observed decreased serum concentration of AFP, the main serological biomarker of dedifferentiation

of hepatocytes that is associated with the development of HCC. This occurred in the frame of attenuated macrophage M1 proinflammatory gene expression in the liver tissue of HCC-treated rats. Tumor-associated macrophages are well known for their trophic abilities and for providing immunosuppressive tumor microenvironment and therefore facilitating tumor progression.⁽³⁵⁾ In that sense, lowering macrophage numbers in liver tissue by means of chemotaxis inhibition or cell death could partially explain the antitumor effects of nanoceria.

Evidence supports that CeO₂NPs have a specific antitumorigenic effect in HCC rats. First, following NPs administration, we observed increased liver apoptotic activity. This is consistent with previous studies describing that after exposure to antioxidant cuprous oxide NPs, lung melanoma cells activate caspase-3 and caspase-9, inducing apoptosis of tumor cells.⁽³⁶⁾ On the other hand, CeO₂NPs also resulted in decreased levels of P-ERK1/2, an essential component of the Ras/Raf/MAPK kinase/ERK signaling pathway. This is among the principal routes controlling cell survival, differentiation, proliferation, growth, angiogenesis, regulation of glucose and lipid metabolism, and inflammation.⁽³⁷⁾

The impact of CeO₂NPs on cell phosphorylation in HCC has not been systematically investigated using untargeted MS-based proteomics. Our initial principal component analysis suggests a global effect of CeO₂NPs over protein phosphorylation in the liver of HCC rats that significantly affected 9.5% of all detected phosphorylation sites. The effect of CeO₂NPs comprised both increased and decreased phosphorylation. The administration of CeO₂NPs affected kinases involved in signaling pathways related to apoptosis, cell proliferation, migration, and survival such as p21 (RAC1) activated kinase 2, eukaryotic elongation factor 2 kinase, protein tyrosine kinase 2/focal adhesion kinase 2, and NIMA-related kinase 9. Interestingly, a gene ontology analysis showed an enrichment of proteins linked to RNA splicing and cell-cell adhesion in the subset of proteins whose phosphorylation were significantly regulated after CeO₂NPs treatment. Splicing is a process frequently deregulated in cancer cells because it can regulate the function of key proteins involved in apoptosis, proliferation, angiogenesis, and migration.⁽³⁸⁾ In this regard, CeO₂NPs treatment that reduced cell proliferation caused both an increase and a decrease in the phosphorylation of proteins involved in splicing. Cell adhesion is also a

process heavily deregulated in cancer cells with multiple proteins involved in cell–cell adhesion considered as tumor suppression or oncogenes.⁽³⁹⁾ Our gene ontology analysis indicates that CeO₂NPs produce a large effect on the phosphorylation pattern of proteins involved in cell–cell adhesion with proteins presenting both overphosphorylation and downphosphorylation, suggesting an alteration in this biological process. We observed a reduced phosphorylation of two other cell surface proteins involved in cell adhesion, CD44 and Itgb4.

A hallmark of cancer cells is dysregulation of FA metabolism to support proliferation.⁽⁴⁰⁾ Accordingly, total serum TG and cholesterol were found to be significantly decreased in HCC rats. Highly proliferative cancer cells have strong lipid and cholesterol avidity; consequently, these cells either increase the uptake of exogenous lipids or overactivate their endogenous synthesis.⁽⁴¹⁾ Excessive lipids and cholesterol in cancer cells are stored in lipid droplets as cholesteryl esters,⁽³⁷⁾ which is in agreement with our findings of increased CE-derived FAs in hepatic HCC tissue. The analysis of principal lipid components also revealed an increase in NEFA probably due to an increased generation to support tumor growth.

The most important effects induced by CeO₂NPs are found in PC-derived FAs. The decrease in PC-PUFAs resulting from CeO₂NPs administration was mostly due to a decrease in AA.⁽⁴²⁾ Phospholipases A₂, C, and D can mediate the release of esterified AA from cellular phospholipids, a process which already seems incremented in HCC. Free AA can be metabolized through enzymatic reactions or act as a second messenger in signal transduction pathways⁽⁴³⁾; some of these pathways were demonstrated to be significantly up-regulated in our HCC rats. After nanoceria treatment, the decrease in esterified PC-AA was more pronounced. This phenomenon seems to be related to the increase of apoptosis in these rats because free AA is able to promote the activation of sphingomyelinase and the apoptotic process.⁽⁴⁴⁾

CeO₂NPs treatment reversed the increase in NEFA-derived, TG-derived, and CE-derived LA in HCC rats. LA, one of the most abundant FAs in all lipid components, has been reported to change the metabolism of intrahepatic CD4⁺ T cells, leading them to apoptosis and, thus, contributing to HCC development.⁽⁴⁴⁾ Neoplastic hepatocyte lesions have been associated with changes in the PUFA profile,

which are likely due to an abnormal essential FA metabolism involving Δ -6 desaturase (Δ -6D).⁽⁴³⁾ The activity and expression of this desaturase are regulated by the intracellular redox state.⁽⁴⁵⁾ This suggests that the restoration of normal hepatic levels of LA in the HCC rats treated with CeO₂NPs could result from the reactivation of Δ -6D activity due to the reduction in oxidative stress.

The translation of the antitumorigenic effects induced by CeO₂NPs into a clinically significant improvement was assessed by investigating the effect of CeO₂NPs on survival. Treated HCC rats showed a clear amelioration in this parameter. To date, tyrosine kinase inhibitors, such as sorafenib, lenvatinib, cabozatinib, or regorafenib, as well as the antiangiogenic antibody ramucirumab, are considered effective therapies in patients with advanced HCC.⁽⁴⁶⁾ The effect of CeO₂NPs on overall survival was similar to that observed with sorafenib, which indicates that these NPs are at least as effective as sorafenib under the conditions studied. The combination of both treatments did not result in an additional improvement in survival in comparison to each treatment administered alone. CeO₂NPs and sorafenib likely interfere with common signaling pathways, such as angiogenesis through vascular endothelial growth factor signaling, which would explain why the combination of both compounds did not result in any additional effect. The effects of CeO₂NPs on the ERK1/2 signaling pathway, the modulation of the phosphorylation state of a high number of peptides, and their manifestations on cell proliferation and apoptosis mirror some of the abundant data reported on sorafenib effects.⁽⁴⁷⁾

For a comprehensive understanding of whether the behavior of CeO₂NPs in the human liver resembles that observed in rats with HCC, we administered nanoceria to human livers under *ex vivo* normothermic perfusion. The *ex vivo* experiments confirmed that CeO₂NPs have high avidity for human liver because they accumulate in the target tissue readily after administration. The NPs were found both free and within intracellular, single-membrane, endosome-like organelles. The elemental analysis combined with the STEM helped us to confirm their presence and distinguish them from endogenous structures and artifacts in the tissue. Moreover, *in vitro* experiments with the HepG2 cell line confirmed the uptake and retention of

CeO₂NPs by human hepatocyte cancer cells mostly in endosome-like bodies.

In conclusion, these results indicate that the anti-oxidant properties of CeO₂NPs partially revert cell mechanisms involved in tumor progression and significantly increase survival in HCC rats, indicating that this inorganic nanomaterial represents an effective treatment in experimental HCC. These findings suggest that CeO₂NPs alone or in combination with the current molecular targeted therapies could be effective at stopping or attenuating the tumoral progression in patients with HCC.

Acknowledgment: We thank the Scientific and Technology Centers of the University of Barcelona (CCiT-UB) for their contribution to the ultrastructural examination and the subcellular location of CeO₂NPs in human liver samples and HepG2 human hepatocytes.
