Abstract: Ten mononuclear rare earth complexes of formula [La(btfa)(H₂O)] (I), [La(btfa)(4,4'-Mbt2bipy)] (2), [La(btfa)(5,5'-Me2bipy)] (3), [La(btfa)(2,2′-Me2bipy)] (4), [La(btfa)(terpy)] (5), [La(btfa)(phen)(EtOH)] (6), [La(btfa)(4,4′-Me2bipy)(EtOH)] (7), [La(btfa)(2-benzpy)(MeOH)] (8), [Tb(btfa)(4,4′-Me2bipy)] (9) and [Eu(btfa)(2)] (10), where btfa = 4,4,4-trifluoro-1-phenylbutane-1,3-dionato anion, 4,4′-Mbt2bipy = 4,4′-dimethyl-2,2′-bipyridine, 4,4′-Me2bipy = 4,4′-dimethyl-2,2′-bipyridine, 5,5′-Me2bipy = 5,5′-dimethyl-2,2′-bipyridine, terpy = 2,2′,6′,2′-terpyridine, phen = 1,10-phenanthroline, 2-benzpy = 2-(2-pyridyl)benzimidazole, Hpy = pyridiniumH cation) have been synthesized and structurally characterized. The complexes display coordination numbers (CN) eight for 1, 2, 9, 10, nine for 5, 6, 7, 8 and ten for 3 and 4. The solid-state luminescence spectra of Tb-9 and Eu-10 complexes showed the same characteristic bands predicted from the Tb(III) and Eu(III) ions. The Overall Quantum Yield measured (ΦTOT) at the excitation wavelength of 371 nm for both compounds yielded 1.04% for 9 and up to 34.56% for 10.

Keywords: lanthanum(III); terbium(III); europium(III); β-diketone anion; luminescence; crystal structure

1. Introduction

The coordination chemistry of lanthanides has been the subject of extensive studies over the last two decades as these compounds revealed unusual physicochemical characteristics including fluorescent and potent magnetic properties because of their unique 4f electrons [1–4]. Many of the lanthanide compounds have been used in technological devices such as smartphones, solar cells, solid-state lasers emitting in the UV, visible, or near-infrared (NIR) regions, optical glasses, batteries, increasing the memory storage of computers [1,2,5–12] as well as chiral sensing of biomolecules [13]. The small ionic size of lanthanide ions makes them have the ability to replace metal ions inside protein complex such as calcium [14]. Lanthanide-tagged proteins are valuable for investigating protein structure, function, and dynamics [14,15]. Additionally, lanthanides, especially, La3+ and Gd3+ block different types of calcium, potassium, and sodium channels in human and animal neurons [16]. The lanthanide(III) ions or their compounds binding to DNA and
cleavage DNA is a growing topic to understand mutations that lead to cancer and treatment of this disease [17,18]. Furthermore, the in vitro and vitro cytotoxic activities of some Ln(III) complexes especially, La(III) and Ce(III), which showed very promising anti-tumor activity [19,20].

The general electronic configurations [Xe] 4f

\(^{n}\) of lanthanide ions (Ln(III)) generate a variety of electronic energy levels [1–3,12]. The electronic transitions within the 4f orbitals are shielded by the filled 5s\(^2\)5p\(^6\) subshells, and as a result they are becoming less sensitive to the chemical environments around Ln(III) ions. Consequently, each lanthanide ion exhibits narrow and characteristic 4f\(^{n}\)-4f\(^{n+1}\) transitions except La\(^{3+}\) (4f\(^0\)) and Lu\(^{3+}\) (4f\(^{14}\)). The 4f\(^{n}\)-4f\(^{n+1}\) transitions in Ln(III) complexes are Laporte forbidden leading to weak light absorption [2,4] and hence the process of direct excitation of metal electrons is very inefficient. However, the most prominent feature in the lanthanide compounds is through the “antenna effect” in which the ligand or linker is used for the excitation process followed by energy transfer to the lanthanide centers, from which the emission occurs and, in this case, the forbidden 4f-transitions can be fairly enhanced, i.e., partly circumvented [1–3,12]. Charge-transfer, CT of complex

\([\text{Hbtfa}]^{2−}\) in the presence of NaOH (1:3:3), followed by the addition of H\(_2\)O and stirring at room temperature afforded the diaqua complex \([\text{La(btf)}}_2\) \([\text{H}_2\text{O}])\) \((1)\) in a reasonable high yield (78\%). This complex was used as the precursor for the preparation of the La(III)-pyridyl adducts 2–8. Reactions of \([\text{La(btf)}}_3\) \([\text{H}_2\text{O}])\) \((1)\) with two equivalents of 4,4′-Me\(_2\)bipy and 5,5′-Me\(_2\)bipy in ethanol and/or ethanol-acetone mixture resulted in the formation of bis(bipyridyl) adducts 3 and 4, respectively. Mono(pyridyl) adducts were obtained when 1:1 molar ratio of the diaqua complex 1 and 4,4′-Me\(_2\)bipy, terpy, phen and 4,4′-Me\(_2\)bipy were used leading to the isolation of \([\text{La(btf)}}_2\) \((4,4′\text{-M}_{2}\text{bipy})\) \((2)\), \([\text{La(btf)}}_3\) \((\text{terpy})\) \((3)\), \([\text{La(btf)}}_3\) \((\text{phen})(\text{EtOH})\) \((4)\) and \([\text{La(btf)}}_3\) \((4,4′\text{-M}_{2}\text{bipy})(\text{EtOH})\) \((5)\), respectively in a yield varies from 37 to 74\%. A similar product was also formed, \([\text{La(btf)}}_3\) \((2\text{-bpy})(\text{MeOH})\) \((6)\), when MeOH was used as a solvent. On the other hand, the in situ reaction of Tb\((\text{NO}_3)\)_3 \(6\text{H}_2\text{O}\), Hbtfa, Et\(_3\)N and 4,4′-Me\(_2\)bipy in ethanol produced the yellow crystalline compound \([\text{Tb(btf)}}_3\) \((4,4′\text{-Me}_{2}\text{bipy})\) \((9)\) in 75\% yield, whereas the corresponding reaction of Eu\((\text{NO}_3)\)_3 \(6\text{H}_2\text{O}\), five equivalents of Hbtfa and excess pyridine (py) in ethanol led to the separation of the anionic complex \([\text{Eu(btf)}}_4\] \((10)\) (62\% yield). Probably, we should mention that, with the exception of complex 9, attempts made to obtain good quality crystals suitable for X-ray analysis of
Tb(III) and Eu(III)-pyridyl adducts, similar to those obtained in this work were failed and as a result only the two complexes 9 and 10 were synthesized and characterized. However, complex [Eu(btfa)(4,4′-Me₂bipy)] similar to the Tb-9 was reported [31]. The purity of the ten compounds was confirmed by elemental microanalyses (see experimental section) and also with checking their X-ray powder diffractions (Figures S1–S10, Supplementary Material Section) as well as X-ray structural analysis.

Scheme 1. Structure of 4,4,4-trifluoro-1-phenylbutane-1,3-dione (Hbtfa).

The IR spectra of the complexes under investigation display general characteristic pattern that is similar to most Ln(III) compounds containing tris- and tetrakis(β-ketonato) anions [24–26]. The strong vibrational band observed over the frequency range 1604–1614 cm⁻¹ of the complexes 1–10 is assigned to the stretching frequency of the coordinated carbonyl, ν(C=O) [24–26]. The weak broad band observed around 3460 cm⁻¹ reveals the ν(O-H) stretching frequency of the coordinated aqua ligands in 1.

2.2. Description of the Crystal Structures 1–10

Partially labelled molecular plots and coordination figures of the title complexes 1–10 are presented in Figures 1–3 and main bond parameters are summarized in Table S1, respectively. Each La(III) center of the neutral and monomeric complexes 1–8 are ligated by six oxygen donor atoms of three btfa β-diketonato ligand anions. Coordination number 8 in 1 is achieved by two oxygen atoms of terminal aqua ligands, and in 2 by the two N-donor atoms of the 4,4′-Mt₂bipy chelating ligand. Their La-N/O bond lengths vary in the range from 2.407(3) to 2.6690(14) Å. The coordination number ten around La1 in 3 and 4 is completed by 4 nitrogen donor atoms of two chelating 4,4′-Me₂bipy and 5,5′-Me₂bipy ligands, respectively. Their La-N/O bond distances are in the range from 2.4911(14) to 2.8637(18) Å.

The CN = 9 was found in the La(III) complexes 5, 6, 7 and 8. In 5 the LaN₃O₅ “chromophore” around the central La1 is achieved by ligation of one tridentate terpy chelating ligand, whereas the LaN₂O₃ “chromophore” in 6–8 complexes is completed by ligation of two N-donor atoms of one chelating phen molecule and an O atom of terminal EtOH in 6, two N-donor atoms of one chelating 4,4′-Me₂bipy molecule and an O atom of terminal EtOH in 7 and by ligation of two N-donor atoms of one 2-benzpy molecule and an O atom of terminal MeOH ligand. The La-N/O bond distances in the nine-coordinated compounds 5–8 are in the range from 2.4588(17) to 2.7736(18) Å. The O-La1-O bite angles of the β-diketonate groups fall in the range from 65.96(5) to 71.56(9)° in 1–8, and the N-La1-N bite angles of the chelating ligand molecules in 2–8 vary from 55.86(5) to 61.40(7)°.
Figure 1. (a–d) Perspective view and coordination figure of 1–4, respectively.

Figure 2. (a–d) Perspective view and coordination figure of 5–8, respectively.
In a similar coordination fashion, the two complexes [Tb(btfa)$_3$(4,4′-Me$_2$-bipy)] (9) and (Hpy)[Eu(btfa)$_4$] (10) display CN = 8 around. In 9, the Tb1 is formed by six oxygen atoms of three btfa anions and two N atoms of a 4,4′-Me$_2$-bipy chelating ligand. The Tb-N/O bond distances vary from 2.417(3) to 2.547(3) Å, the O-Tb-O angles from 71.33(10) to 72.12(10) Å and the N1-Tb1-N2 bite angle is 63.08(10)°. In 10, the Eu1 in the complex anion [Eu(btfa)$_4$]$^-$, the eight-coordination is achieved by the oxygen atoms of four β-diketonato anions. The bond lengths in the EuO$_8$ coordination figure vary from 2.346(6) to 2.451(5) Å, with values of 2.381(6), 2.403(5), 2.451(5), 2.346(6), 2.362(6), 2.364(5), 2.388(6) and 2.361(6) Å, for Eu1-O1 to Eu1-O8, respectively. The O-Eu-O bite angles of the btfa ligands range from 70.81(18) to 73.0(2)°. These bond parameters are in the same range observed for other [Eu(btfa)$_4$]$^-$ complex anions with tetrabutylammonium [Eu-O from 2.340(10) to 2.435(7) Å] [32] and 4-dimethylaminopyridinium [Eu-O from 2.356(2) to 2.524(2) Å] [33] as counter cations.

The continuous shape measure theory with the SHAPE software [34,35] was used to analyze the degree of distortion of the coordination polyhedra in 1–10 from their ideal polyhedron geometry. For title compounds with CN = 8 with respect to ideal eight-vertex polyhedra intermediate distortion between various coordination polyhedra is observed. For LaO$_6$ of 1 the lowest shape measures (CShM’s) values correspond to triangular dodecahedron (TDD-8), Square antiprism (SAPR-8) and Biaugmented trigonal prism (BTPR-8) with values of 0.380, 2.933 and 3.009. For TbN$_2$O$_6$ of 9 the corresponding values are 0.589, 1.993 and 2.372, respectively and 0.360, 1.992 and 2.394 in EuO$_8$ of 10, whereas in case of LaN$_2$O$_6$ of 2 the values are 2.179, 1.263 and 2.391, i.e., the lowest value observed for square antiprism (SAPR-8).

For LaO$_6$N$_4$ polyhedra of 3 and 4 with respect to ideal ten-vertex polyhedra intermediate distortion is observed with lowest CShM’s for Sphenocorona J87 (JSPC-10) with values of 1.587 and 1.697, respectively. The next lowest continuous shape measures correspond to Bicapped square antiprism J17 (JBSAPR-10) and Tetradecahedron (2:6:2) (TD-10).

For title compounds 5–8 with CN = 9 with respect to ideal nine-vertex polyhedra intermediate distortion between various coordination polyhedra is observed. For LaN$_3$O$_6$ of 5 and LaN$_2$O$_7$ of 6 the lowest CShM’s values correspond to spherical capped square antiprism (CSAPR-9), tricapped trigonal prism (TCTPR-9), Muffin (MFF-9), and gyroelongated square pyramid (J10) with values of 0.795, 0.840, 1.374 and 1.495, respectively for the former complex, and 0.554, 1.083, 1.497 and 1.884 in 6. For LaN$_2$O$_7$ of 7 the lowest CShM’s values correspond to Muffin (MFF-9), spherical capped square antiprism (CSAPR-9) and capped square antiprism (J10) with values of 0.785, 0.979 and 1.828. For LaN$_2$O$_7$ of 8 the lowest CShM’s values correspond to spherical capped square antiprism (CSAPR-9), tricapped trigonal prism (TCTPR-9) and Muffin (MFF-9) with values of 1.192, 1.244 and 1.455, respectively.

Packing plots of 1–10 are presented as Figures S11–S20 in the Supplementary Materials section. The O-H groups of the aqua and alcohol ligands in 1, 6–8 form hydrogen bonds of type O-H···O and O-H···F; the N-H group of 2-benzpy molecule in 8 forms a hydrogen bond of type N-H···O (Table 1). The aromatic ring systems in these complexes are involved
in numerous \( \pi \cdots \pi \) ring
\( \cdots \) ring and C-H/F
\( \cdots \) ring interactions, which further stabilize the packing of the mononuclear complexes (Tables S2–S11).

### 2.3. Luminescence Emission of Terbium (9) and Europium (10) Complexes

The photoluminescence of 9 and 10 was measured in the solid state at room temperature. For Compound 9 (Figure 4) the spectrum shows an intense and broad band with two peak maxima at 300 and 371 nm corresponding to the \( \pi \rightarrow \pi^* \) transitions of 4,4’-Me2bipy and btfa\(^-\) ligands, respectively [36]. The excitation wavelength for the emission spectrum (\( \lambda_{\text{em}} \)) is 371 nm. The first emission peak at 492 nm could be attributed to \( ^5\text{D}_4 \rightarrow ^7\text{F}_6 \) transition, whereas the most intense band located at 543 nm is attributed to \( ^5\text{D}_4 \rightarrow ^7\text{F}_5 \) transition. These were followed by another three peaks at 593, 614 and 650 nm, which could be assigned to \( ^5\text{D}_4 \rightarrow ^7\text{F}_4, ^5\text{D}_4 \rightarrow ^7\text{F}_3 \) and \( ^5\text{D}_4 \rightarrow ^7\text{F}_2 \) transitions, respectively. Moreover, the very weak bands observed around 700 nm can be assigned to the \( ^5\text{D}_4 \rightarrow ^7\text{F}_1 \) and \( ^5\text{D}_4 \rightarrow ^7\text{F}_0 \) transitions [37–39].

![Figure 4](image-url)  
**Figure 4.** Excitation (left) and emission (right) spectra of compound 9.

For compound 10 (Figure 5), the excitation spectrum monitored at 613 nm (\( ^5\text{D}_0 \rightarrow ^7\text{F}_2 \)) reveals an intense broad band at 371 nm due to the \( \pi \rightarrow \pi^* \) transition from the coordinated btfa\(^-\) ligands to the Eu(III) ion. In addition, the narrow, which was observed at 464 nm is assigned to \( ^7\text{F}_0 \rightarrow ^5\text{D}_2 \) transition from the central europium ion [40]. Emission spectrum of 10 (Figure 5) recorded at excitation wavelength \( \lambda_{\text{ex}} = 371 \) nm exhibits the characteristic
bands that arise from Eu(III) f-f transitions. At 580 nm (Figure 5, inset left), $^5D_0\rightarrow^7F_0$ transition appeared as the weakest intense peak. Furthermore, the pure magnetic dipole transition $^5D_0\rightarrow^7F_1$ at 591 nm, in which its intensity is practically independent of the Eu$^{3+}$ environment, is divided into two components due to crystal field splitting of the $^7F_1$ level [41]. The emission spectra of 10 is revealing four main bands at 591 ($^5D_0\rightarrow^7F_1$), 613 ($^5D_0\rightarrow^7F_2$), 656 ($^5D_0\rightarrow^7F_3$) and 704 ($^5D_0\rightarrow^7F_4$) [31,40,42]. The emission peak centered at 613 nm, which is the strongest peak and corresponds to the hypersensitive band $^5D_0\rightarrow^7F_2$ is the one responsible for the observed emission color of the sensitized europium compound. The intensity ratio between $^5D_0\rightarrow^7F_2$ and $^5D_0\rightarrow^7F_1$ is 5.45 is indicating that the emission color is shifted to the orange range and the Eu(III) ion is not placed in a position with inversion symmetry according to the coordination geometry obtained from the SHAPE measurement (TDD8-D2d) [43]. In addition, the emission spectrum was recorded at $\lambda_{ex} = 464$ nm ($^5D_2\leftarrow^7F_0$) (Figure S21). The luminescence spectrum showed the same characteristic bands from the europium ion when excited at the longer wavelength with a measured luminescence Quantum Yield (QY) in the solid state of 14.82% proposing the possible use of the compound for biomedical applications.

![Figure 5. Excitation (black line) and emission (orange line) spectra of 10. Inset, left, shows an enlarged view of the $^5D_0\rightarrow^7F_0$ transition and right the emission color of the complex under UV light radiation.](image)

</table>
The measured QY at 371 nm of the Terbium compound (9) is relatively low, indicating a poor efficiency of the sensitization effect due to a potential overlap between the ligand triplet state and the terbium $^5D_4$ emission resonance level that leads to back energy transfer [44–46]. On the other hand, the sensitization efficiency of the btfa ligand to Eu$^{3+}$ transfer ($\eta_{\text{sens}}$) for 10 is 78.2% $\eta_{\text{sens}}$. This reflects the efficiency in which the energy is transferred from the excited states of the ligand to the excited states of the lanthanide metal and is defined as $\eta_{\text{sens}} = \Phi_{\text{TOT}}/\Phi_{\text{Ln}}$. The calculated Eu$^{3+}$ intrinsic quantum yield (\(\Phi_{\text{Ln}}\)) for compound 10 is 44.19%. Since the excitation band corresponding to the $^5L_6 \leftarrow ^7F_0$ f-f center transition, around ~395 nm, is not seen in the excitation spectra, $\Phi_{\text{Ln}}$ could not be measured in order to compare it with the calculated one [44]. The $\Phi_{\text{Ln}}$ is calculated by $\Phi_{\text{Ln}} = \tau_{\text{obs}}/\tau_{\text{rad}}$, where $\tau_{\text{rad}}$ is the radiative lifetime that is referred to the lifetime of an emissive compound in the absence of non-radiative processes and this value is 2.229 ms for 10. Due to Eu$^{3+}$ pure magnetic dipole character of the $^5D_0 \rightarrow ^7F_1$ transition, $\tau_{\text{rad}}$ can be calculated using a simpler equation:

$$\frac{1}{\tau_{\text{rad}}} = A_{MD,0} n^2 \left( \frac{I_{\text{TOT}}}{I_{MD}} \right)$$  

(1)

where $I_{\text{TOT}}/I_{MD}$ is the ratio of integrated area of $^5D_0$ emission bands from the corrected emission spectra to the pure magnetic dipole $^5D_0 \rightarrow ^7F_1$ integrated emission band and $A_{MD,0}$ and $n$ are a constant equal to 14.65 s$^{-1}$ and the refractive index in where the sample is measured (1.517 for solid state), respectively [40,47]. The obtained results agree with other Eu(III) [31,32,36,48] and Tb(III) [49,50] $\beta$-diketonate compounds.

3. Experimental Section

3.1. Materials and Physical Measurements

4,4,4-Trifluoro-1-phenylbutane-1,3-dione, 4,4'-dimethoxy-2,2'-bipyridine, 4,4'-dimethyl-2,2'-bipyridine, 5,5'-dimethyl-2,2'-bipyridine, 2,2':6',2'-terpyridine, 1,10-phenanthroline, 2-(2-pyridyl)benzimidazole, were purchased from TCI Europe N. V. (Zwijndrecht, Belgium). Lanthanum(III) nitrate salts, Ln(NO$_3$)$_3$·6H$_2$O (Ln = La, Tb and Eu) were obtained from Strem Chemicals (Kehl, Germany) and the other chemicals were of analytical grade quality. Infrared spectra of solid complexes were recorded on a Bruker Alpha P (platinum-ATR-cap) spectrometer (Bruker AXS, Madison, WI, USA). Elemental microanalyses were carried out with an Elementar Vario EN3 analyser (Langenselbold, Germany). The X-ray powder patterns (See supplement materials: Figures S1–S10). were measured on a Bruker D8 Advance diffractometer (Bruker AXS, Madison, WI, USA) with a LynxEye detector in Bragg–Brentano $\theta/2\theta$ geometry, with the sample dispersed thinly on a zero-background Si sample holder, $\lambda$(CuK$\alpha$) = 1.54060 Å, scans from 5° to 50° 2θ, stepsize 0.02°.
3.2. Syntheses of the Complexes

[La(btfa)$_3$(H$_2$O)$_2$] (1). To an ethanolic solution (40 mL) containing NaOH (6 mmol, 0.240 g, 6.0 mmol) was added Hbtfa (1.300 g, 6.0 mmol) and La(NO$_3$)$_3$·6H$_2$O (0.866 g, 2.0 mmol). The solution was stirred for 1 h at room temperature. Then, 80 mL of deionized water was added to the reaction mixture and stirred overnight. The colorless precipitate, which was separated was collected by filtration and dried at 80 °C (yield: 1.28 g, 78%). Anal. Calc. for C$_{30}$H$_{22}$F$_3$LaO$_8$ (820.38 g/mol): C, 43.9; H, 2.7; N, 0.0. Found: C, 42.8; H, 2.6; N, 0.0%. Selected IR bands (ATR-IR, cm$^{-1}$): 3658 (m), 3460 (br), 1608 (s), 1574 (s), 1526 (m), 1487 (m), 1465 (m), 1328 (s), 1244 (m), 1180 (s), 1143 (s), 1072 (m), 944 (m), 778 (s), 578 (s), 450 (w).

[La(btfa)$_3$(4,4′-Me$_2$bipy)] (2). The complex [La(btfa)$_3$(H$_2$O)$_2$] (90 mg, 0.110 mmol) and 4,4′-dimethoxy-2,2′-bipyridine (28 mg, 0.129 mmol) were dissolved in ethanol (20 mL) and the solution was stirred for ~2 h, at room temperature. The reaction mixture was then filtered and allowed to crystallize at room temperature. After ten days, the light pink single crystals, which separated were collected by filtration and dried in air (yield: 68 mg, 51.5%). Anal. Calc. for C$_{21}$H$_{24}$F$_3$LaO$_8$ (1017.62 g/mol): C, 52.3; H, 3.2; N, 0.0%. Selected IR bands (ATR-IR, cm$^{-1}$): 3658 (m), 3460 (br), 1608 (s), 1574 (s), 1526 (m), 1487 (m), 1465 (m), 1328 (s), 1244 (m), 1180 (s), 1143 (s), 1072 (m), 944 (m), 778 (s), 578 (s), 450 (w).

[La(btfa)$_3$(4,4′-Mt$_2$bipy)] (2). The complex [La(btfa)$_3$(H$_2$O)$_2$] (90 mg, 0.110 mmol) and 4,4′-dimethyl-2,2′-bipyridine (42 mg, 0.227 mmol) were dissolved in ethanol (20 mL) and the solution was stirred for ~3 h, at room temperature. The reaction mixture was then filtered and allowed to crystallize at room temperature. After twenty days, the small colourless single crystals of [La(btfa)$_3$(4,4′-Me$_2$bipy)]$_2$, which separated were collected by filtration and dried in air (yield: 103 mg, 71.1%). Anal. Calc. for C$_{25}$H$_{28}$F$_3$LaO$_8$ (1152.82 g/mol): C, 56.5; H, 3.5; N, 0.0%. Selected IR bands (ATR-IR, cm$^{-1}$): 1614 (s), 1578 (m), 1529 (m), 1487 (m), 1459 (m), 1314 (m), 1281 (s), 1245 (m), 1179 (m), 1138 (s), 1074 (m), 1038 (w), 1023 (m), 940 (w), 831 (m), 772 (s), 699 (s), 628 (m), 577 (m), 508 (m).

[La(btfa)$_3$(4,4′-Me$_2$bipy)$_2$] (3). The diaqua complex 1 (103 mg, 0.126 mmol) and 4,4′-dimethyl-2,2′-bipyridine (60 mg, 0.324 mmol) were dissolved in 40 mL ethanol/acetone (4:1) and the solution was stirred for ~3 h, then filtered and allowed to crystallize at room temperature. After seven days, the well grown colorless single crystals of [La(btfa)$_3$(4,4′-Me$_2$bipy)$_2$], which separated were collected by filtration and dried in air (yield: 103 mg, 71.1%). Anal. Calc. for C$_{25}$H$_{28}$F$_3$La$_2$N$_2$O$_8$ (1152.82 g/mol): C, 56.3; H, 3.7; N, 4.9. Found: C, 56.5 H, 3.5; N, 4.7%. Selected IR-bands (ATR-IR, cm$^{-1}$): 1611 (s), 1578 (m), 1531 (m), 1514 (w), 1486 (m), 1473 (m), 1441 (w), 1308 (m), 1280 (s), 1237 (m), 1179 (s), 1124 (s), 1074 (m), 1026 (w), 941 (w), 915 (w), 821 (s), 758 (s), 700 (s), 576 (s), 514 (m).

[La(btfa)$_3$(5,5′-Me$_2$bipy)$_2$] (4). The diaqua complex 1 (115 mg, 0.140 mmol) and 5,5′-dimethyl-2,2′-bipyridine (60 mg, 0.324 mmol) were dissolved in 40 mL ethanol/acetone (4:1) and the solution was stirred for ~2 h, then filtered and allowed to crystallize at room temperature. After seven days, the well grown colorless single crystals, which separated were by filtration and dried in air (yield: 139 mg, 86.0%). Anal. Calc. for C$_{25}$H$_{28}$F$_3$La$_2$N$_2$O$_8$ (1152.82 g/mol): C, 56.3; H, 3.7; N, 4.9. Found: C, 56.4 H, 3.5; N, 4.8%. Selected IR-bands (ATR-IR, cm$^{-1}$): 1614 (s), 1593 (m), 1569 (m), 1522 (w), 1506 (w), 1384 (m), 1284 (s), 1240 (m), 1195 (m), 1179 (m), 1122 (s), 1067 (w), 1038 (w), 956 (w), 922 (w), 863 (w), 786 (s), 680 (s), 646 (w), 563 (s), 471 (w).

[La(btfa)$_3$(terpy)] (5). The complex [La(btfa)$_3$(H$_2$O)$_2$] (106 mg, 0.129 mmol) and 2,2′:6′,2″-terpyridine (32 mg, 0.137 mmol) were dissolved in 30 mL ethanol/acetone (3:1) and the solution was stirred for ~3 h, then filtered and allowed to crystallize at room temperature. After ten days, the isolated well shaped colorless single crystals were collected by filtration and dried in air (yield: 68 mg, 51.5%). Anal. Calc. for C$_{45}$H$_{30}$F$_5$La$_2$N$_2$O$_8$ (1017.62 g/mol): C, 53.1; H, 2.9; N, 4.1. Found: C, 52.9 H, 3.0; N, 4.2%. Selected IR-bands (ATR-IR, cm$^{-1}$): 1612 (s), 1597 (m), 1574 (s), 1551 (m), 1519 (m), 1471 (s), 1316 (m), 1281 (s), 1239 (m), 1174 (m), 1144 (m), 1126 (s), 1071 (m), 1023 (w), 809 (w), 793 (w), 761 (s), 695 (s), 650 (w), 576 (s), 501 (w).

[La(btfa)$_3$(phen)(EtOH)] (6). This complex was isolated as colorless single crystals using 1,10-phenanthroline (1:1 molar ratio) instead of 4,4′-Me$_2$bipy and a procedure similar to that described for complex 3 (yield: 37.3%). Anal. Calc. for C$_{48}$H$_{32}$F$_5$La$_2$N$_2$O$_7$ (1101.62 g/mol): C, 52.3; H, 3.2; N, 2.8. Found: C, 52.2 H, 3.1; N, 2.9%. Selected IR-bands (ATR-IR, cm$^{-1}$): 1609 (s), 1573 (s), 1519 (m), 1487 (m), 1468 (s), 1371 (w), 1317 (m), 1285 (s), 1243 (m), 1178 (m), 1131 (s), 1074 (m), 1025 (w), 941 (m), 843 (w), 762 (s), 700 (s), 578 (s), 510 (w).
[La(btfa)₃(4,4′-Me₂bipy)(EtOH)] (7). A procedure similar to that described for complex 3 was used but equimolar amounts of 4,4′-dimethyl-2,2′-bipyridine (23 mg, 0.124 mmol) and [La(btfa)₃(H₂O)]₂ were used. The complex [La(btfa)₃(4,4′-Me₂bipy)(EtOH)] was obtained as colorless single crystals after twelve days (yield: 73 mg, 62.9%). Anal. Calc. for C₄₄H₃₉F₅LaN₂O₇ (1014.66 g/mol): C, 52.1; H, 3.6; N, 2.8. Found: C, 52.3 H, 3.4; N, 2.9%. Selected IR-bands (ATR-IR, cm⁻¹): 1610 (s), 1579 (w), 1534 (w), 1487 (w), 1451 (s), 1317 (m), 1291 (s), 1236 (m), 1183 (m), 1136 (m), 1074 (m), 1033 (m), 1007 (m), 920 (w), 833 (s), 761 (s), 697 (m), 629 (m), 576 (m), 514 (w).

[La(btfa)₃(2-benzpy)(MeOH)] (8). A mixture containing La(NO₃)₃·6H₂O (37 mg, 0.085 mmol), NaOH (11 mg, 0.275 mmol), 2-(2-pyridyl)benzimidazole (16 mg, 0.082 mmol) and 4,4,4-trifluoro-1-(2-phenyl)-1,3-butanedion (Hbtfa) (64.8 mg, 0.30 mmol) was added to another ethanolic solution (10 mL) of 4,4,4-trifluoro-1-phenyl-1,3-butanedion (Hbtfa) (318.5 mg, 1.25 mmol) and pyridine (py) (118.6 mg, 0.25 mmol) was added to another ethanolic solution (10 mL) containing 4,4,4-trifluoro-1-(2-phenyl)-1,3-butanedion (Hbtfa) (64.8 mg, 0.30 mmol). The mixture solution was stirred for 30 min, then filtered and allowed to stand at ambient temperature. The yellow crystals, suitable for X-ray analysis, which obtained after two weeks were collected by filtration and dried in air. (yield: 74 mg, 30% based on Tb(NO₃)₃·6H₂O).

3.3. Single Crystal X-ray Diffraction Analysis

Single-crystal data of 1–8 complexes were measured on an APEX II CCD diffractometer (Bruker-AXS; Madison, WI, USA) and those of 9 and 10 on a D8 Venture (Bruker-AXS, Madison, WI, USA). Table S12 summarizes crystallographic data, intensity data collection, and structure refinement specifications. Data collections were performed at 100(2) K with Mo–Kα radiation (λ = 0.71073 Å); computer programs APEX and SADABS [51,52] were used for data reduction, LP, and absorption corrections. The program library SHELX [53,54] was used for solution (direct methods) and refinement (full-matrix least-squares methods on F²). Anisotropic displacement parameters were applied to all non-hydrogen atoms. H atoms (Uiso) were obtained from difference Fourier maps. Additional software: Mercury [55] and PLATON [56]. CCDC deposition numbers: CCDC 2099334–CCDC 2,099,343 for 1–10, respectively.
3.4. Luminescence Measurements

Solid state fluorescence spectra of compounds 9 and 10 were recorded on a Horiba Jobin Yvon SPEX Nanolog fluorescence spectrophotometer (Fluorolog-3 v3.2, HORIBA Jovin Yvon, Cedex, France) equipped with a three slit double grating excitation and emission monochromator with dispersions of 2.1 nm/mm (1200 grooves/mm) at room temperature. The steady-state luminescence was excited by unpolarized light from a 450 W xenon CW lamp and detected at an angle of 22.5° for solid state measurement by a red-sensitive Hamamatsu R928 photomultiplier tube. The instrument was adjusted to obtain the highest Background-to-noise ratio. Spectra were corrected for both the excitation source light intensity variation (lamp and grating) and the emission spectral response (detector and grating).

The excited state decay curves were measured in the same instrument in the phosphorescence mode using a 450 W xenon pulsed lamp (λ = 371 nm, 1.5 ns pulse). The measured decays were analyzed using the Origin software package. Both decay curves fitted monoexponentially: \( I(t) = I_0 \exp\left(-\frac{t}{\tau}\right) \). The fit quality was determined by the \( \chi^2 \) method of Pearson. Absolute Quantum Yield measurements were acquired in the G8 Quantum Integrating Sphere from GMP with an interior reflective coating made of Spectralon® (Zürich, Switzerland). Then, the \( \Phi_{TOT} \) was calculated following Equation (2):

\[
\Phi = \frac{E_c - E_c(\text{blank})}{I_a - L_c}\]

where \( L_a \) is the calculated area of the outgoing amount of light without interaction with a sample (blank) at the used \( \lambda_{exc} \) and \( L_c \) after interaction with the sample. \( E_c \) refers to the calculated area from the emission spectrum of the sample and \( E_c(\text{blank}) \) from the emission spectrum of the Blank.

4. Conclusions

The interaction of Ln(NO₃)₃·6H₂O (Ln = La(III) or Tb(III)) with 4,4,4-trifluoro-1-phenylbutane-1,3-dione (Hfta) in ethanol, methanol and/or mixed ROH-acetone and Et₃N or NaOH in the stochiometric ratio 1:3:3 afforded the neutral mononuclear tris(β-ketonato) compounds, where in the presence di-nitrogen donor or terpy ligands allow the central Ln(III) ions display a variety of CN (8–10) and geometries: [La(btfa)₃(4,4'-Me₂bipy)] (2), [La(btfa)₃(4,4'-Me₂Me₂bipy)] (3), [La(btfa)₃(5,5'-Me₂bipy)] (4), [La(btfa)₃(terpy)] (5), [La(btfa)₃(phen)(EtOH)] (6), [La(btfa)₃(4,4'-Me₂bipy)(EtOH)] (7), [La(btfa)₃(2-benzpy)(MeOH)] (8) and [Tb(btfa)₃(4,4'-Me₂bipy)] (9). When excess Hfta is used, the tetrakis(β-ketonato) anionic complex ([Hpy][Eu(btfa)₄]) (10) was isolated. This trend in reactions of Ln(III) salts and β-diketonate derivatives seems to be universal, where many compounds and pyridyl adducts of similar structural formulas have been isolated and structurally characterized [24–26,31,57–61].

Studying the luminescence of the tris(β-ketonato) Tb (9) and tetrakis(β-ketonato) Eu (10) complexes revealed efficient energy transfer in the visible region from the ligands to the central Ln(III) ion. Similar luminescent emission trend was observed in the UV and visible regions in other related β-ketonate derivatives [24–26,57–61]. However, it should be mentioned that incorporating strong chelating polypyridyl ligands into the Ln(III)-tris(β-ketonato) significantly enhances the emission luminescent properties of the compounds in the visible and NIR regions [25,62]. Recently, it has been demonstrated that incorporation of β-diketonate into calix [4] arene ligand skeletons enhances their corresponding lanthanide-centered luminescence and magnetic relaxivity properties [63,64], which make them suitable candidates, especially Gd(III), in magnetic resonance imaging (MRI) and in developing nanomaterials for sensing and bioimaging [64].
