

TITLE

The Tilburg Frailty Indicator: a psychometric systematic review

ABSTRACT**Background**

The Tilburg Frailty Indicator (TFI) is one of the most prominent multidimensional frailty assessment instruments. This review aimed to critically appraise and summarise its measurement properties.

Methods

Reports were eligible if they included results of studies aimed at developing the TFI or evaluating its measurement properties. We performed a literature search in MEDLINE, CINAHL, and PsycINFO databases from their inception until September 17, 2020. We also searched grey literature databases. We assessed the methodological quality of the included studies using the “COSMIN Risk of Bias”. The measurement properties were evaluated using specific criteria. We graded the quality of the evidence using a GRADE approach.

Results

Fifty-five studies were included. We found moderate sufficient evidence for TFI content validity, although it is still insufficient for the comprehensiveness of its items. TFI construct validity was based on sufficient evidence from a single study of its structural validity as well as multiple hypothesis-testing for construct validity studies with inconsistent results. We did not find any studies that assessed cross-cultural validity. The TFI showed high sufficient concurrent validity with the comprehensive geriatric assessment. We identified several studies assessing its predictive validity for adverse frailty-related outcomes, although most of the evidence from these studies was insufficient. We did not find any studies that assessed the responsiveness of TFI scores.

Conclusions

The TFI is a simple measurement instrument that may be helpful in the assessment of frailty. However, more studies are needed to strengthen its usefulness as a clinical decision-making tool.

Aged, Frailty, Patient-Reported Outcome Measures, Psychometrics, Systematic Review

1. INTRODUCTION

Identifying older people who are frail or at risk of becoming frail has become the centrepiece of geriatric care in recent years (Hoogendijk et al., 2019). This identification can be approached from three perspectives: predominantly clinical, multidimensional, and holistic functional (Junius-Walker et al., 2018). Regarding the clinical perspective, frailty is understood as a clinical state determined by a series of signs and symptoms (Xue, 2011); however, this perspective may be insufficient to capture the full range of potential criteria determining frailty

(Junius-Walker et al., 2018; Sezgin et al., 2019). Moreover, other researchers suggest that frailty should not be limited to the physical domain and they advocate carrying out a multidimensional assessment that includes other factors such as psychological, cognitive, emotional, social or spiritual (Junius-Walker et al., 2018; Sezgin et al., 2019). On the other hand, World Health Organisation recommends holistic functional perspective, which includes a multidimensional approach to frailty. Nevertheless, its focus is on “total person functioning” rather than deficits and diseases (Junius-Walker et al., 2018). Because of this, it seems that the multidimensional perspective would be the most appropriate to assess all the possible factors involved in frailty (Sezgin et al., 2019).

Among the instruments available to perform a multidimensional assessment of frailty, the Tilburg Frailty Indicator (TFI) (Gobbens et al., 2010) is prominent. Existing systematic reviews show that it is one of the most robust instruments, especially to use in primary care (Pialoux et al., 2012; Sutton et al., 2016). However, these systematic reviews conclude that further in-depth evaluation of the measurement properties of TFI is needed. Moreover, these previous reviews do not cover all available evidence due to their completion date and focus on evaluating several measurement instruments rather than on a single instrument. Therefore, a specific systematic review on TFI may be more efficient in identifying all available evidence.

Developing and improving an effective individual care plan that meets the person’s life goals involve a regular and multidimensional assessment of the person’s needs (Dent et al., 2019). Multidimensional measures of frailty can provide more insight into these needs and enable tailored care management. The TFI is a multidimensional frailty assessment tool widely used in both clinical practice and geriatric research, so there is a need to update the available evidence to determine its suitability for this purpose. This systematic and psychometric review aimed to critically appraise and summarise the measurement properties of TFI to support evidence-based recommendations on its use and identify gaps in knowledge on its measurement properties, which can be used to design new studies.

2. METHODS

We conducted this psychometric systematic review following the COSMIN initiative (Mokkink et al., 2018; Prinsen et al., 2018; Terwee et al., 2018). The review is reporting according to the Preferred Reporting Items for Systematic reviews and Meta-Analyses (PRISMA) 2020 (Page et al., 2021) statement and the PRISMA literature search extension (Rethlefsen et al., 2021). The review protocol was registered in the International Prospective Register of Systematic Reviews (PROSPERO) on January 4, 2021 (registration number: [CRD42021224427](https://www.crd.york.ac.uk/PROSPERO/record/CRD42021224427)); no changes have been made to the protocol.

2.1. Search strategy and eligibility criteria

We performed a comprehensive literature search in MEDLINE (PubMed), CINAHL (EBSCOhost), and PsycINFO (EBSCOhost) databases from their inception until September 17,

2020. We also searched the grey literature on OpenGrey and Grey literature Report databases. Reports were eligible if they included results of studies aimed at developing the TFI or evaluating one or more of its measurement properties. Studies that only use the TFI as an outcome measure (e.g., clinical trials) or those used to validate another measurement instrument were excluded. Only full-text reports were included because often the minimum information about a study is found in the abstracts. Likewise, for our MEDLINE (PubMed) search, we added a highly sensitive filter to identify studies on measurement properties (Terwee et al., 2009). We imposed no language restrictions on any of the searches. The reproducible searches for all databases are available at <https://doi.org/10.5281/zenodo.5513482>. We manually screened reference lists of included studies to identify additional studies.

2.2. Selection process

We imported the retrieved references into the Rayyan QCRI web application program (Ouzzani et al., 2016). Two reviewers removed duplicates using the program's duplicate identification strategy and then manually. These two reviewers independently assessed the titles and abstracts of the retrieved records against the eligibility criteria. If a record seemed relevant to at least one of the reviewers, the full text of the report was independently reviewed by these two reviewers. Reviewers discussed conflicts over inclusion, and a third reviewer was consulted in case of not reaching a consensus.

2.3. Data collection process and study risk of bias assessment

We assessed the methodological quality of the included studies using the "COSMIN Risk of Bias" (available at: https://www.cosmin.nl/wp-content/uploads/COSMIN-RoB-checklist-V2-0-v17_rev3.pdf). The evaluation was carried out by each member of the review team independently. All assessments were compared, discussed, and agreed at regular meetings. Evaluation data were collected using forms designed by COSMIN (available at https://cosmin.nl/wp-content/uploads/Scoring-form-COSMIN-boxes_april_final.xlsx). Regarding criterion validity, we agreed, based on the available literature on frailty and following the COSMIN guidelines, that only comprehensive geriatric assessment (CGA) could be considered a gold standard for TFI (Hoogendijk et al., 2019; Mokkink et al., 2018; Parker et al., 2018; Prinsen et al., 2018). Predictive validity was assessed, as most of the identified studies aimed to assess this property; however, only longitudinal studies were assessed. We did not assess cross-sectional studies for this property; even though the authors described them as predictive validity studies, we considered them for construct validity.

2.4. Synthesis methods

The measurement properties were evaluated using specific criteria developed and agreed by experts (Prinsen et al., 2018). This assessment was carried out based on the number of studies available and the consistency of their results. We pooled the internal consistency results of the TFI scores by the Meta-Essentials tool (Suurmond et al., 2017) for correlational data version

1.5. We chose random-effects models based on the diversity of populations studied and in the expectation that internal consistency coefficients would differ. The meta-analyses were run with the Fisher-transformed values, which are transformed back into normal correlation coefficients for presentation (van Rhee et al., 2015). The extent and impact of between study heterogeneity were assessed by the τ^2 and the I^2 statistics, respectively. We explored possible causes of variation of results across studies by subgroup analyses based on the mode of administration. We summarised the rest of the measurement properties qualitatively.

The quality of the evidence was graded using a “Grading of Recommendations Assessment, Development and Evaluation (GRADE)” approach modified by COSMIN (Prinsen et al., 2018). As with the assessment of studies’ quality, all these assessments were made independently by each review team member and subsequently compared, discussed, and agreed at regular meetings.

3. RESULTS

The literature search and study selection process is detailed in Figure 1. A total of 55 studies were included; a study had two reports (Hayajneh, 2019, 2016). The summary characteristics of the first study (TFI development) and all included studies are shown in Table 1 and Supplementary file Table 1. Twenty of the 55 studies were from The Netherlands, 17 from other European countries, ten from Asian countries, five from Brazil, one from Turkey, and two were multi-country studies. All studies assessed the measurement properties of part B of the TFI (described in Table 1). In addition, the five reports that were excluded and the reasons for exclusion are listed in Supplementary file Text 1.

The results of the methodological quality assessment of each study on a measurement property using the COSMIN Risk of Bias checklist (Mokkink et al., 2018) are shown in Supplementary file Table 2 and Table 2. Supplementary file Table 3 provides the ratings of each study against the criteria for good measurement properties (Prinsen et al., 2018). Finally, Table 3 summarises the evidence and its grade of quality by using the GRADE approach (Prinsen et al., 2018).

3.1. Content validity

Description and origin of the construct to be measured are clear, as well as the target population and the context of use. The TFI was developed based on previous research on frailty, but only experts were involved (Gobbens et al., 2010). Therefore, it appears that its development was not performed on a sample representing the target population. Comprehensibility and comprehensiveness are tested in a prefinal form of the instrument by representatives of professional disciplines ($n=10$) and by people aged 75 years and older ($n=33$), but these samples were not clearly described. No adjustment was necessary as this pilot test indicated that this version of the instrument was clear and comprehensive. However, the method and approach used to analyse data were not reported. For these reasons, the total quality of instrument design

and the pilot test performance were rated as inadequate and doubtful, respectively. This meant that the total rating of the instrument development was inadequate (see Supplementary file Table 2).

We identified 12 studies that analysed content validity aspects (see Table 2). Eleven of these studies assessed the comprehensibility of TFI versions translated into other languages. Among these studies, the study of the Danish version was the most salient (Andreasen et al., 2014). The quality of nine studies was assessed as doubtful mainly because the methodology's crucial aspects were not sufficiently clarified. One study on the TFI's Turkish version (Topcu et al., 2019) was assessed as inadequate because it did not describe that a cognitive interview or pilot test had been conducted in the target population. Moreover, in this study, the comprehensibility of the instrument was assessed by ten geriatricians. Only one study assessed aspects linked to the relevance and comprehensiveness of the instrument (Andreasen et al., 2015). In this study conducted with the TFI's Danish version, participants confirmed that the instrument covered most aspects of frailty. However, they identified aspects that they believed were not covered. The methodological quality of this study was rated as doubtful because it did not describe the experience with qualitative methods of the interviewers.

In summary (see Table 3), the content validity of the TFI was considered sufficient with moderate quality evidence, as the methodological quality of the studies was mostly doubtful. Evidence on comprehensiveness was considered insufficient as one content validity study indicated that the instrument did not cover important aspects related to frailty; in contrast, the evidence on the relevance and comprehensibility of the instrument was considered sufficient, although, concerning the latter aspect of content validity, the quality of evidence was considered high as the methodological quality of one of the content validity studies was adequate.

3.2. Construct validity

One study assessed the structural validity (Vrotsou et al., 2018) of the TFI, and 30 studies performed hypotheses testing for its construct validity. We did not identify any study that assessed its cross-cultural validity. Structural validity was analysed in the Spanish TFI version, and the results indicated a good fit of the three-factor model. The methodological quality of this study was rated very good, so the evidence on this measurement property was graded as high. We identified a total of 250 hypotheses for construct validity of which we considered 183 (73%) to be confirmed according to the criteria proposed by COSMIN (Prinsen et al., 2018). Nevertheless, the results were inconsistent, so we did not grade the evidence.

3.3. Criterion validity

Concurrent validity with CGA was assessed in two studies (Mazoochi et al., 2020; Si et al., 2020), for which the evidence was rated as sufficient with a high-quality grade. Several studies assessed the predictive validity of TFI for different adverse frailty-related outcomes such as higher health care use, disability, mortality, lower quality of life or falls. We also identified one

study that used a composite outcome variable with unequal importance of events such as readmission or death (Andreasen et al., 2018). The most frequent follow-up period was one year and two years. In some studies, it was six months, four years, seven years, and 12 years. One study analysed the TFI prediction for in-hospital mortality (Chong et al., 2017). The percentage lost to follow-up, in studies providing this information, was less than 20% in ten studies and higher in seven. Health care use was assessed using a wide range of variables: hospital admission, hospitalisation, unplanned readmission, receiving personal care or nursing care or informal care, general practitioner visits, contacts with health care professionals, residential care facilities, or institutionalisation. In most of these studies, the participants self-reported these variables, which contributed to the study's methodological quality being rated as doubtful. Concerning disability, all the identified studies, except one that used the Katz index (Gonzalez-Colaço Harmand et al., 2017), used the Groningen Activity Restriction Scale. Quality of life was measured in identified studies with the brief version of the World Health Organisation Quality of Life (WHOQOL-BREF) questionnaire. The evidence for TFI predictive validity was rated as sufficient for 12-year disability (Gonzalez-Colaço Harmand et al., 2017) and one-year mortality prediction (Chong et al., 2018; Daniels et al., 2012), the quality of this evidence was graded as low and moderate, respectively (see Table 3). It was rated as insufficient for all other adverse frailty-related outcomes studied.

3.4. Reliability

Nineteen studies assessed the internal consistency of TFI scores. The methodological quality of these studies was mostly rated as very good, except for three studies that only reported overall internal consistency coefficient instead of each of three TFI domains (Metzelthin et al., 2010; Topcu et al., 2019; Uchmanowicz et al., 2014). We, therefore, rated the methodological quality of these three studies as inadequate. The pooled results showed that only the physical domain had sufficient evidence in this measurement property with a moderate quality due to its inconsistency (see Table 3). Likewise, only the results of studies in which the TFI was administered by interview were shown to be consistent. Test-retest reliability was assessed in nine studies. Statistical analyses were approached by treating the response options as continuous or dichotomous, whereby the studies provide information on intraclass correlation coefficient as well as Cohen's kappa index. However, one study assessed this property using Pearson's correlation coefficient (Gobbens et al., 2010). The methodological quality of six studies was rated as doubtful mainly because these studies did not provide evidence that participants were stable, it was unclear whether the test conditions were similar, or the time interval was not appropriate. The time interval was 20 weeks in one study, so its methodological quality was considered inadequate (Freitag et al., 2016). Two studies were of adequate methodological quality (Santiago et al., 2013; Vrotsou et al., 2018). We rated the overall evidence as inconsistent, so we did not grade its quality. Only one study assessed the measurement error of

TFI scores (Vrotsou et al., 2018). In this study, the limits of agreement of scores were calculated, but there was no information about the minimal important change, so this evidence was rated indeterminate.

3.5. Responsiveness

We did not identify any study that assessed the responsiveness of a TFI change score.

4. DISCUSSION

This psychometric review was conducted to assess the quality of TFI measurement properties. We found moderate sufficient evidence for TFI content validity, although it is still insufficient for aspects such as the comprehensiveness of its items. TFI construct validity was based on sufficient evidence from a single study of its structural validity, as well as multiple hypothesis-testing for construct validity studies with inconsistent results. However, we did not find any studies that assessed cross-cultural validity. Regarding criterion validity, the TFI showed high sufficient concurrent validity with the CGA. We also identified a substantial number of studies assessing its predictive validity for adverse frailty-related outcomes, although most of the evidence from these studies was insufficient. Internal consistency of scores was the most assessed measurement property; however, only the physical domain scale showed sufficient moderate evidence. We did not find any studies that assessed the responsiveness of TFI scores.

This review has included a much larger number of studies on the TFI compared to other reviews (Pialoux et al., 2012; Sutton et al., 2016). Focusing on a single measurement instrument has allowed for a more in-depth analysis. Furthermore, the fact of not using language limits may also have contributed to the identification of a more significant number of studies. On the other hand, scoring and grading the quality of methods, the interpretation of results and the grading of evidence is a subjective process. However, all included articles were independently reviewed by the reviewers and agreed by consensus amongst the reviewer team. This process helped to resolve discrepancies and reduce variability in interpretation.

In patient-reported outcome measures such as TFI, the target population is the most appropriate assessor of the content validity of a measurement instrument. The target population's comprehensibility of the TFI items has been evaluated in different studies due to the existence of multiple language versions. However, the assessment of the relevance and comprehensiveness of its items by the target population has been scarcely evaluated. We found only two studies that evaluated these content validity aspects (Andreasen et al., 2015; Gobbens et al., 2010). Andreasen et al. (2015) find that most of the TFI items are relevant to older people; however, some items in the TFI physical domain do not seem relevant to them, such as those related to unintentional weight loss or hand strength. They also observe that the TFI does not consider some important aspects for this population, such as pain, sleep disturbances, spirituality, or meaningful activities.

We identified that structural validity was assessed in a single study (Vrotsou et al., 2018) which confirmed a three-factor model for three TFI domains. However, it is surprising that no further studies have been found that analyse this measurement property since such a widely studied measurement instrument. In contrast, many studies have been carried out to analyse the convergent and discriminative validity of TFI scores. Multiple measurement instruments and variables were used for this purpose. It also highlights the large number of hypotheses tested in some studies. Hypotheses for construct validity were confirmed at a high rate (73%), but inconsistent results were observed regarding the association between TFI scores and variables measuring similar or related constructs. Moreover, most studies used *P*-values rather than to assess whether the magnitude of correlations or observed differences were similar or greater than expected (Prinsen et al., 2018). We did not find any studies that analysed cross-cultural validity of the TFI despite the numerous adaptations and translations that have been carried out. This type of validity is essential to determine the equivalence of scores between the original population and the new target population (Prinsen et al., 2018).

We found two studies showing good concurrent validity of TFI with CGA (Mazoochi et al., 2020; Si et al., 2020). This finding has important implications, as CGA is a time-consuming and high-resource intensive process (Hoogendijk et al., 2019; Parker et al., 2018) that can be problematic in some healthcare settings such as primary care. In these settings, the TFI may be a simpler and more feasible tool to capture similar aspects of frailty. We identified a significant number of TFI validation studies for adverse frailty-related outcomes prediction, but their results are inconclusive. Measuring the predictive validity of a frailty measurement instrument is no easy matter. Although most people remain in their baseline frailty state at a follow-up of 1-5 years, a substantial proportion (up to 37%) experience at least one transition, including both worsening and improvement of the frailty state (Hoogendijk et al., 2019). Therefore, there is a need to carry out validation studies that consider frailty as a dynamic process.

Only the TFI physical domain subscale showed sufficient internal consistency of its scores. One possible explanation for this might be that the internal consistency coefficients are highly dependent on the number of items and the two remaining subscales have a tiny number of items. An alternative explanation is that the psychological and social domains are poorly comprehensive, as reported by Andreasen et al. (2015). We identified a substantial number of studies that administered the TFI by interview even though it was designed to be self-administered. One interesting finding is that these results were much more inconsistent when the TFI was self-administered than when it was interviewer-administered. This indicates a possible effect of the mode of administration of the TFI on their data. This influence has been described in the literature, and it may be necessary to conduct experimental studies to determine the origin, magnitude, and direction of this influence (Bowling, 2005). Results in test-retest reliability were inconsistent, probably due to the variability of different methodological aspects

of the studies, such as the lack of evidence of whether respondents were stable, the different time intervals used, and above all the fact that the instrument was not administered under similar conditions on both occasions. Test-retest reliability is an essential requirement of all measurement instruments in clinical practice and research, so this is a measurement property that needs further investigation. On the other hand, in order to evaluate the measurement error, it is necessary to have information on the minimal important change, defined as the smallest change in score that people consider important (Prinsen et al., 2018). We found no information on this issue, so there is also a need to generate evidence on it.

Responsiveness was not explored in any of the studies identified. The lack of assessment of this measurement property is common in frailty measurement instruments (Hoogendijk et al., 2019). However, it is a very relevant measurement property, as clinicians and researchers need measurement instruments that can be used to monitor changes in frailty over time.

5. CONCLUSIONS

The TFI is a simple measurement instrument that may be helpful in the assessment of frailty, especially in settings where time and resources are limited. However, there are important issues for future research, and more studies are needed to strengthen its usefulness as a clinical decision-making tool. A patient-reported outcome measure must be valid for a wide range of uses in different populations, and each use may require new evidence. However, most studies on the TFI focus on analysing the same measurement properties and other properties such as structural validity, cross-cultural validity, reliability, and responsiveness have received much less attention. Moreover, it would be interesting to establish the methodologies and evaluation criteria for testing hypotheses for construct validity. In this way, more homogeneous results would be obtained, which would give more strength to available evidence. On the other hand, it would also be desirable to conduct studies that focus on confirming fewer but strongly supported hypotheses. Finally, it is essential to highlight the importance of generating more evidence regarding the content validity of the TFI, especially in aspects related to the comprehensiveness of its items from the perspective of people who are frail.

Figure 1. PRISMA 2020 Flow-Chart of Study Selection (Page et al., 2021)

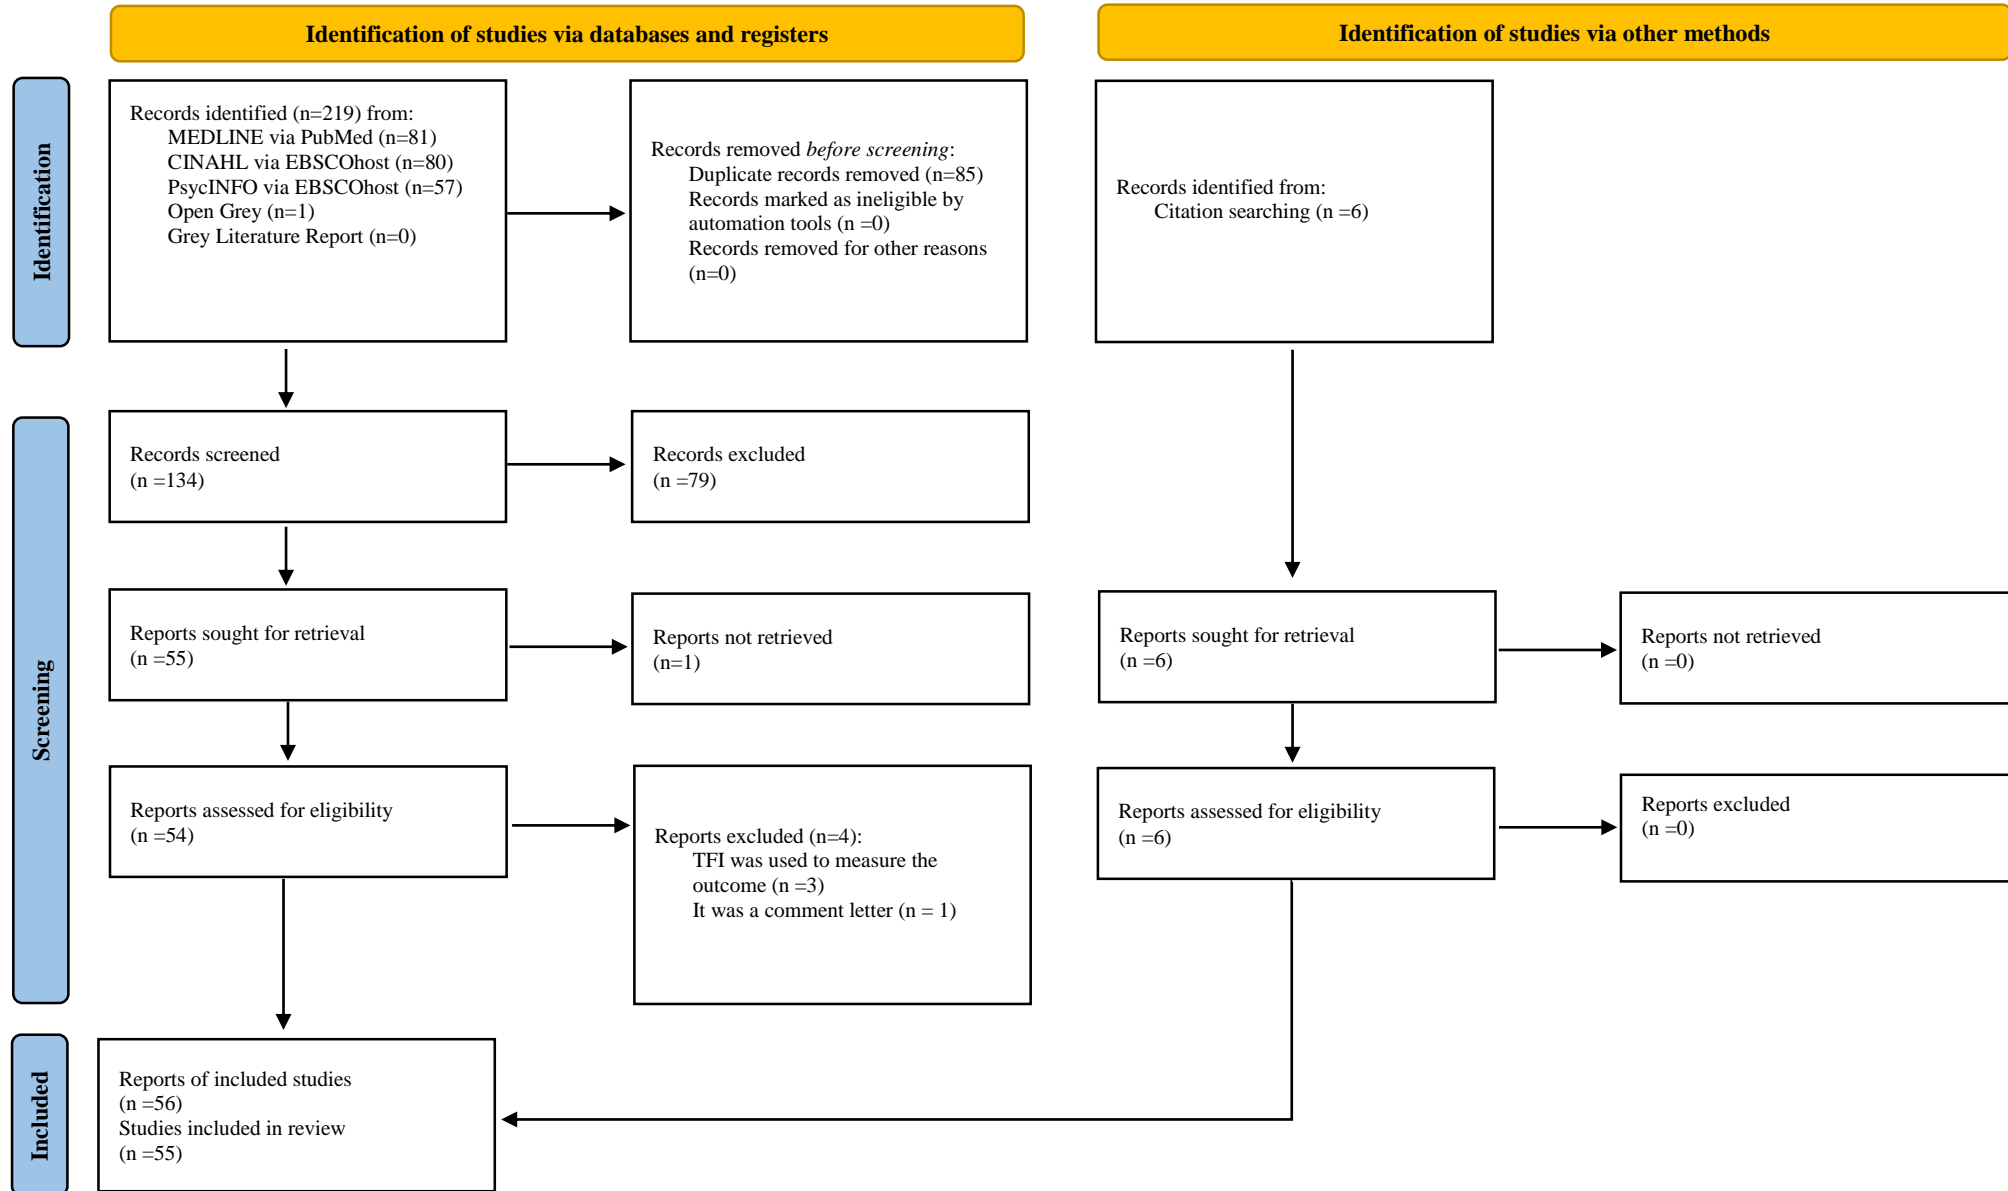

Table 1. Main characteristics of the Tilburg Frailty Indicator (Gobbens et al., 2010)

Target population	Mode of administration	Recall period	(Sub)scale (s) (number of items)	Response options	Range of scores/scoring	Original language	Available translations
Community-dwelling older people	Self-administered	Now	It consists of 2 parts: - Part A contains ten questions on determinants of frailty and diseases (multimorbidity) - Part B contains 15 questions divided into three domains of frailty: physical (8 questions), psychological (4 questions), and social (3 questions)	- Yes/No (11 questions) - Yes/ Sometimes /No (4 questions)	- The score for frailty and the three domains of frailty are determined by adding items' responses belonging to each scale. The response options "sometimes" and "yes" are grouped into a single score. - Score ranges from 0 to 15. - Frailty cut off point ≥ 5 - Higher score=Higher degree of frailty	Dutch	-Arabic (Jordan & Saudi Arabia) -Chinese (China) -Croatian -Danish -English (UK) -French (France) -German -Greek -Italian -Persian -Polish -Portuguese (Brazil & Portugal) -Spanish (Spain) -Turkish

V, Very good; A, Adequate; D, Doubtful; I, Inadequate. Empty cells indicate that this measurement property had not been assessed.

Table 3. Summary of findings

Measurement property	Summary or pooled result	Overall rating	Quality of evidence
Content validity	Not applicable	Sufficient	Moderate: TFI development study inadequate quality, and there are multiple content validity studies of doubtful quality available
<i>Relevance</i>	Not applicable	Sufficient	Moderate: TFI development study inadequate quality, and there is one content validity study of doubtful quality available
<i>Comprehensiveness</i>	Not applicable	Insufficient	Moderate: TFI development study inadequate quality, and there is one content validity study of doubtful quality available
<i>Comprehensibility</i>	Not applicable	Sufficient	High: TFI development study inadequate quality, and there is at least one content validity study of adequate quality available
Structural validity	3 factors: CFI=0.961 and RMSEA=0.035	Sufficient	High: There is one study of very good quality available
Internal consistency			
<i>Physical domain</i>	Global: coefficient 0.69 (95% CI, 0.67 to 0.72), n= 7736, I ² =61.5%	Sufficient	Moderate: There are multiple studies of very good quality available, and there is moderate inconsistency
	Self-administered mode: coefficient 0.68 (95% CI, 0.65 to 0.71), n=6961, I ² =62.4%	Sufficient	Moderate: There is multiple studies of very good quality available, and there is moderate inconsistency
	Interviewer-administered mode: coefficient 0.74 (95% CI, 0.69 to 0.78), n=775, I ² =0.0%	Sufficient	High: There is multiple studies of very good quality available
<i>Psychological domain</i>	Global: coefficient 0.54 (95% CI, 0.49 to 0.58), n=7307, I ² =68.1%	Insufficient	Moderate: There is multiple studies of very good quality available, and there is moderate inconsistency

Measurement property	Summary or pooled result	Overall rating	Quality of evidence
	Self-administered mode: coefficient 0.55 (95% CI, 0.51 to 0.60), n=6532, I ² =68.1%	Insufficient	Moderate: There is multiple studies of very good quality available, and there is moderate inconsistency
	Interviewer-administered mode: coefficient 0.47 (95% CI, 0.37 to 0.56), n=775, I ² =26.0%	Insufficient	Moderate: There is multiple studies of very good quality available, and there is low inconsistency
<i>Social domain</i>	Global: coefficient 0.41 (95% CI, 0.34 to 0.48), n=7503, I ² =89.9%	Insufficient	Low: There is multiple studies of very good quality available, and there is high inconsistency
	Self-administered mode: coefficient 0.39 (95% CI, 0.30 to 0.48), n=6728, I ² =91.9%	Insufficient	Low: There is multiple studies of very good quality available, and there is high inconsistency
	Interviewer-administered mode: coefficient 0.47 (95% CI, 0.34 to 0.57), n=775, I ² =53.1%	Insufficient	Moderate: There is multiple studies of very good quality available, and there is moderate inconsistency
Cross-cultural validity/Measurement invariance	No info available		
Reliability	ICC range 0.23 to 0.99	Inconsistent	
Measurement error	LoA were calculated but MIC was not defined	Indeterminate	
Criterion validity			
- <i>Concurrent validity</i>	2 out of 2 hypotheses confirmed (100%)	Sufficient	High: There are studies of very good quality available
- <i>Predictive validity</i>	Health care use: 17 out of 45 hypotheses confirmed (38%)	Insufficient	High: There are studies of very good quality available
	Disability (all studies): 5 out of 12 hypotheses confirmed (42%)	Insufficient	High: There are studies of very good quality available
	Disability (one year follow-up): 4 out of 7 hypotheses confirmed (57%)	Insufficient	Moderate: There are studies of doubtful quality available
	Disability (two-year follow-up): 1 out of 2 hypotheses confirmed (50%)	Insufficient	High: There are studies of very good quality available
	Disability (12-year follow-up): 1 out of 1 hypothesis confirmed (100%)	Sufficient	Low: There is one study of doubtful quality available
	Mortality (all studies): 6 out of 9 hypotheses confirmed (67%)	Insufficient	High: There are studies of very good quality available

Measurement property	Summary or pooled result	Overall rating	Quality of evidence
	Mortality (one-year follow-up): 2 out of 2 hypotheses confirmed (100%)	Sufficient	Moderate: There are studies of doubtful quality available
	Mortality (two-year follow-up): 1 out of 1 hypothesis unconfirmed (0%)	Insufficient	High: There are studies of very good quality available
	Mortality (\geq four-year follow-up): 3 out of 5 hypotheses confirmed (60%)	Insufficient	High: There is one study of very good quality available
	QoL: 1 out of 4 hypotheses confirmed (25%)	Insufficient	Moderate: There are studies of doubtful quality available
	Falls: 1 out of 4 hypotheses confirmed (25%)	Insufficient	Moderate: There are studies of doubtful quality available
Hypotheses testing for construct validity	183 out of 250 hypotheses confirmed (73%)	Inconsistent	
Responsiveness	No info available		

CFI, Comparative Fit Index; CI, Confidence Interval; ICC, Intraclass Correlation Coefficient; LoA, Limits of Agreement; MIC, Minimal Important Change; QoL, Quality of life; RMSEA, Root Mean Square Error of Approximation; TFI, Tilburg Frailty Indicator
