#### WEBSITE: www.ub.edu/irea/ • CONTACT: irea@ub.edu

The Research Institute of Applied Economics (IREA) in Barcelona was founded in 2005, as a research institute in applied economics. Three consolidated research groups make up the institute: AQR, RISK and GiM, and a large number of members are involved in the Institute. IREA focuses on four priority lines of investigation: (i) the quantitative study of regional and urban economic activity and analysis of regional and local economic policies, (ii) study of public economic activity in markets, particularly in the fields of empirical evaluation of privatization, the regulation and competition in the markets of public services using state of industrial economy, (iii) risk analysis in finance and insurance, and (iv) the development of micro and macro econometrics applied for the analysis of economic activity, particularly for quantitative evaluation of public policies.

IREA Working Papers often represent preliminary work and are circulated to encourage discussion. Citation of such a paper should account for its provisional character. For that reason, IREA Working Papers may not be reproduced or distributed without the written consent of the author. A revised version may be available directly from the author.

Any opinions expressed here are those of the author(s) and not those of IREA. Research published in this series may include views on policy, but the institute itself takes no institutional policy positions.

#### Abstract

Previous studies in energy stock markets have analyzed market connectedness using aggregate indexes and focusing on developed markets. We depart from the extant literature and we focus our attention on companies listed on emerging stock markets and examine connectedness from the firm's perspective. Using a two-step approach, we remove the common global factors from energy stock returns and estimate the network of global energy stocks in emerging markets. We show that idiosyncratic components are highly relevant for our understanding of risk transmission in energy markets. Moreover, we offer precise diversification alternatives and identify the most systemically important firms and countries.

JEL classification: G15, Q43, Q48.

## **1. Introduction**

The ongoing energy transition to sustainable generation sources has drawn great political and academic attention to the global financial network of energy firms. The connectedness of energy corporations on the world stock market determines not only the market and credit risks to which international investors and banks with share portfolios and loans in the energy sector are exposed, but also the funding opportunities for the operation and innovation of energy firms. Indeed, funding and risk transmission are crucial in a context of change such as that imposed by the energy transition. For instance, a highly integrated market network of energy firms means that there is a considerable degree of risk-sharing across countries enabled by companies listed on a variety of markets, but it also means that there is a high probability of contagion and fewer opportunities for risk diversification in times of crisis and, therefore, a greater likelihood that systemic risk materializes in the global energy sector in times of trouble. For this reason, monitoring the evolution of the global financial network of energy firms and identifying the main actors (both countries and individual firms) in that network are of the utmost importance for global investors and managers of global corporations in the energy sector as well as for policy-makers and regulators.

Despite the large body of literature studying the connectedness and spillovers of energy markets, as well as between these markets and traditional financial markets, two major gaps remain that this study seeks to address. First, when estimating the global financial network of energy companies, we opt to focus our attention on companies listed on the emerging stock exchanges, markets that are typically overlooked or, when included, mentioned only in passing. Second, most studies to date rely on market indices to estimate the financial energy network; however, here, we opt to analyze connectedness from the firm's perspective, given that it represents a more informative, more precise alternative. In terms of methodology, our approach is facilitated by the fact that we are able to leverage recent advances in network estimation based on large vector autoregressions (VARs) and factor models. Our estimates, moreover, control for the presence of unobservable common factors that might simultaneously affect the price of energy firms on global stock markets. In this way, we are able to correct for a common and significant omission in the field, which in our case is fundamental as we deliberately omit developed markets from our network analysis. The approach we adopt allows us to estimate spillovers between individual energy companies listed on the world's emerging stock markets more accurately and to offer more precise policy and portfolio recommendations than previous studies.

Environmental deterioration attributable to the burning of fossil fuels and the transition towards more sustainable forms of production have raised investor awareness and political interest in environmental issues in developed economies and, more recently and with even greater urgency, in emerging economies. Indeed, emerging markets are more frequently and more significantly dependent on the prices of such commodities as oil and coal than are developed markets. In emerging economies, the energy transition directly affects expected government revenues as the latter are frequent shareholders in energy companies. Moreover, energy commodity prices greatly determine domestic current account balances, because

emerging economies are more often than not net exporters of these commodities, especially of oil, coal and natural gas, but also of critical materials for the energy transition, including lithium and cobalt. The Global Status Report on Renewables indicates that the participation of emerging economies in total renewable energy investment has grown significantly and consistently in recent years, above all in China, which accounted for 32% of observed investment in 2018 (Renewables, 2019). In 2020, their renewable energy capacity investment reached USD 153.4 billion, surpassing that of developed countries. This has contributed to a continuing increase in the offsetting of overall investment in fossil fuel-related assets involving investors worth nearly USD 15 trillion (Renewables, 2021). Despite the greater relevance and commitment of emerging market economies to the energy transition, empirical evidence about these factors is scarce. Indeed, to the best of our knowledge, we are the first to focus our research efforts exclusively on energy firms listed on emerging stock markets.

We study connectedness in a large firm-level system comprising 219 energy companies listed on 27 emerging markets. Our analysis is based on weekly data for the period between January 13, 2010 and March 24, 2021. In line with the approach recently developed by Fan et al. (2021) for analyzing large panels of data, we combine sparse VARs and factor models, estimated using principal component analysis (PCA), to estimate connectedness and spillover statistics across energy firms at the global scale. We follow a two-step approach. First, we estimate the common factors in the returns of our large set of energy firms by means of PCA, in keeping with a traditional factor model in econometrics, and, second, we fit the network model proposed by Demirer et al. (2018) to the series of idiosyncratic components of the system (i.e. the residuals of the regression of each stock return on the common factors). This methodology allows us to calculate the spillover statistics proposed by Diebold and Yilmaz (2012, 2014) when the curse of dimensionality is a concern, by reducing the parameter space of the VAR system through the least absolute shrinkage and selection operator (LASSO). We contrast our results at the firm level with results at the country level, the latter being built upon equally weighted index portfolios for each country. In this way, we can assess robust and complementary characteristics of the energy stock network and, all in all, we manage to capture firm heterogeneity in terms of connectedness and evaluate the systemic relevance of each firm and country in our sample.

A vast empirical literature has studied the link between stocks in developed markets and energy commodity markets (Kumar et al. 2012; Reboredo and Ugolini, 2016, 2018; Lundgren et al., 2018; Ferrer at al., 2018; Xia et al., 2019; Kocaarslan and Soytas, 2019; Reboredo et al., 2019; Nasreen et al., 2020; Naeem et al., 2020; Hanif et al., 2021; Geng et al., 2021a, 2021b; Saeed et al., 2021; Gomez-Gonzalez et al., 2022), and although a few studies have analyzed the relationship between stocks in emerging markets and energy commodities (Li and Wei, 2018; Evrim et al., 2020; Demirer at al., 2020), evidence on the latter remains scarce. Moreover, the literature exclusively concerned with energy market connectedness is very recent and is not exempt from methodological limitations. For example, Singh et al. (2019) employ Diebold and Yilmaz's (2012) methodology to model the MSCI energy equity indices of 21 countries in Europe, North and Latin America and Asia-Pacific and find that the energy stock markets of developed countries (mainly North America and Europe) are net transmitters of shocks and have a dominant role in the energy market network. The authors also show that after the global financial crisis, emerging countries, and particularly China, have experienced an increase in their share of total system spillovers. More recently, Tiwari et al. (2021) analyzed connectedness between energy stock markets, using indices from 20 regional blocks. This study used Diebold and Yilmaz's (2014) approach exploiting a time-varying parameter (TVP)-VAR and the LASSO model. Their findings lend support to the conclusions drawn by Singh et al. (2019) by indicating that the energy stock markets of developed countries (i.e. those belonging to the G7 and G12) are the main net transmitters of volatility, while the markets of Southeast Asia, Scandinavia, the Far East and the Americas are net receivers. Despite the relevance of these findings from a methodological point of view, earlier studies have omitted the fact that the connectedness between energy stock markets is determined by both idiosyncratic and systematic factors (i.e. oil, coal, and gas prices, but also global activity, global funding liquidity, etc.). This distinction is fundamental for investment decisions and for identifying real diversification opportunities for international investments. According to traditional finance theory, risk shocks in energy markets attributable to systematic factors cannot be diversified away, while idiosyncratic shocks that affect only a single company or group of companies can, admittedly, at different levels, depending on general market conditions and market structure.

Another methodological limitation of these earlier studies, which we seek to address here, concerns their use of aggregate country or regional indices as their unit of analysis. This level of aggregation does not permit the full incorporation of key heterogeneities at the firm level, critical for understanding risk transmission within a country or between firms listed on different markets (Pham, 2019). Only a few studies have sought to overcome this limitation but they focus primarily on energy markets in developed countries. Restrepo et al. (2018) was one of the first to advocate the use of firm-level data to estimate spillovers in the financial energy network – focusing on 20 oil companies with the largest market capitalization in the US - to construct a network in line with the approach developed by Diebold and Yilmaz (2012). Fuentes and Herrera (2020) study the connectedness between the stock prices of 16 renewable energy companies from the United States, Canada, Brazil, Denmark and China, and various volatility indicators of oil, stocks and gold markets. Exploiting Diebold and Yilmaz's (2014) methodology, the authors conclude that significant and heterogeneous spillovers occur both within and between sectors and renewable energy companies, which are mainly affected by stock market volatility. Foglia and Angelini (2020), in an analysis of 24 renewable energy companies listed on the NASDAQ and MSCI Global Energy Efficiency indices, show that total spillover in the system varied from 21.36% pre-Covid-19 to 61.23% following the onset of the pandemic. Geng et al. (2021a) corroborate the strong connectedness between oil and stock prices for eight renewable energy companies in Europe. All these studies are, nevertheless, limited in terms of the number of firms on which they base their conclusions. For this reason, it proves impossible to assess the systemic relevance to the global stock market of the vast majority of firms in the energy sector (even those with a relatively large market capitalization in their respective domestic markets), which means potentially relevant network nodes are omitted ad hoc without any theoretical or empirical justification. Here, in our calculations, we specifically address this shortcoming by incorporating a total of 219 energy firms.

This study provides three main sets of results. First, we show that emerging energy stock markets are closely integrated even after controlling for global systematic factors. Moreover, we are able to establish the contributions of both systematic and idiosyncratic factors. Second, we provide precise diversification alternatives at both the country and firm levels, related to those countries or firms that are less sensitive to shocks from the rest of the system, or which are located on the periphery of the global energy network. Third, we identify systemically important countries and firms, that is, the actors that generate the largest shocks to the rest of the system or which are more authoritative and central within the emerging market energy network that we estimate.

More specifically, as regards our first set of results, when energy stock returns include the common systematic factors, we show that the system's total connectedness at the country level reaches 61.43%, falling to 24.45% when the effect of these factors is removed and the stock returns are fully idiosyncratic. The corresponding levels of network connectedness when using firm-level data are 82.97 and 39.92%, respectively. This first result is relevant as it highlights two specific characteristics of the global energy network: i) when common factors are not taken into account, energy market spillover estimates are biased upwards, and individual markets and individual firms are identified as being more systemically important than they actually are, because much of the system's variation comes from global factors that affect all markets and firms simultaneously; and, ii) after considering the common factors, idiosyncratic components of energy stock returns continue to be highly relevant for our understanding of risk transmission in energy markets. For this reason, energy markets can be considered vulnerable to episodes of financial spillovers in times of distress.

In the case of our second set of results, if we consider the network from which we have factored out the effects of global energy factors, the countries in its periphery are those that interact less with the rest of the system and which, therefore, offer potentially greater diversification opportunities. This set of countries includes Peru, Bosnia-Herzegovina, South Korea, Thailand, Argentina, Malaysia, Colombia, Chile, Brazil, Indonesia and Russia. At the firm level, greater heterogeneity can be seen between firms from different countries. Companies such as Kohinoor Energy Ltd. (Pakistan), Can Don Hydro Power and Vinh Son Song Hinh Hydropower (Vietnam), Sahacogen Chonburi Public Company Ltd. (Thailand) and Ultrapar Participacoes (Brazil) stand out as investment alternatives that favor portfolio diversification within the energy markets because they receive the lowest spillovers from other firms.

In the third set of results, we find that the main transmitters of shocks at the market level are Romania, India, Vietnam, Pakistan, Mongolia, Philippines, Hong Kong, Turkey, Montenegro, Sri Lanka and Taiwan. In addition, Chinese (Huadian Power International Corporation, Huaneng Power International, China Petroleum & Chemical Corporation) and Brazilian firms (Centrais Eletricas Brasileiras, Petroleo Brasileiro, Centrais Eletricas Brasileiras, Companhia Energetica de Minas Gerais) stand out as the main spreaders of idiosyncratic risks. This means that these markets and firms, located in the core of the network, can induce additional volatility pressures in the system, which are largely unrelated to the global energy factors that affect all stocks simultaneously and which merit special monitoring on the part of corporate risk managers.

The remainder of the paper is structured as follows. Section 2 presents our data and Section 3 provides details of our methodological approach. Section 4 shows our main results and, finally, Section 5 reports the conclusions and implications of our study.

## 2. Data

Stock prices for energy firms (expressed in US dollars) were obtained from Bloomberg for a sample period that runs from January 13, 2010 to March 24, 2021. The sample comprises 219 firms from the energy sector listed in 27 emerging countries, predominantly in Asia. Firms with incomplete records were eliminated from the sample. Appendix 1 provides further details of the firms sampled.

The weekly returns of the energy firms were calculated from Wednesday to Wednesday to mitigate non-synchronous trading issues and weekend anomalies. For the country-level analysis, we constructed equally weighted index portfolios for each country. Table 1 summarizes the descriptive statistics of the weekly portfolio returns at the country level. According to the mean and median values, weekly portfolio returns oscillate around 0 and most are left-skewed. In addition, there is significant heterogeneity between countries in terms of return and risk. In general, the Asian energy stock markets present the lowest risk. Shapiro-Wilk test statistics reject the null hypothesis of normality in all cases and ADF test results indicate that all return series are stationary. Appendix 2 shows the descriptive statistics for the data at the firm level.

*Note:* Statistics are reported as percentage points. Data correspond to equally weighted index portfolio returns for each country. Sample period extends from January 13, 2010 to March 24, 2021. Shapiro-Wilk refers to the Shapiro-Wilk test for the null of normality. ADF corresponds to the Augmented Dickey-Fuller unit root test, which only considers the random walk specification. Superscripts \*\*\*, \*\*, \* indicate statistical significance at the 1%, 5%, and 10% levels, respectively.

#### 3. Methodology

We combine sparse VARs and factor models and adopt a two-step approach. First, in line with Fan et al. (2021), Barigozzi and Brownlees (2019) and other recent studies, we factor out an energy firm's stock returns using PCA. We, then, estimate the network model proposed by Demirer et al. (2018) on the idiosyncratic components of the returns. This approach allows us to calculate the spillover statistics proposed by Diebold and Yilmaz (2012, 2014) for a wide system of stock returns by reducing the parameter space of the VAR system through the LASSO.

We, first, estimate the common factors in the returns of our large set of energy firms via PCA in order to isolate the idiosyncratic components of the system. We estimate the following regression:

$$r_t = \Lambda F_t + U_t \,, \tag{1}$$

where  $r_t$  are the stock returns in time t,  $F_t$  is a vector of latent common factors, and  $U_t$  is an idiosyncratic component described as residual stock returns. Equation (1) estimates the vector containing the factor loadings,  $\Lambda$ , and  $F_t$  for t = 1, ..., T by means of PCA.

Once the stock returns have been filtered from their systematic components, we use the methodological framework developed by Demirer et al. (2018) to study the connectedness between countries or energy firms. Demirer et al. (2018) extend Diebold and Yilmaz's approach (2012, 2014) using LASSO methods, which facilitates the handling of large data sets, selecting and shrinking in optimal ways. Consider a covariance stationary *N*-variable sparse VAR(p) model for the vector of (filtered) energy stock returns  $x_i$ :

$$x_t = \sum_{i=1}^p \Phi_i \, x_{t-i} + \varepsilon_t \quad , \tag{2}$$

where  $\varepsilon_t \sim (0, \Sigma)$  is a vector of non-autocorrelated disturbances. The moving average representation for  $x_t$  is:

$$x_t = \sum_{i=0}^{\infty} A_i \,\varepsilon_{t-i} \quad , \tag{3}$$

where the  $N \times N$  coefficient matrices  $A_i$  obey the recursion  $A_i = \Phi_1 A_{i-1} + \Phi_2 A_{i-2} + \dots + \Phi_p A_{i-p}$  with  $A_0$  being an identity matrix and  $A_i = 0$  for i < 0. The moving average coefficients are relevant to understand the system dynamics and connectedness measures. Next, through the LASSO algorithm, the parameters in  $\Phi_i$  can be obtained by solving:

$$\widehat{\Phi} = \underset{\Phi}{\arg\min\sum_{t=1}^{T} \left( x_t - \sum_{i=1}^{p} \Phi_i x_{t-i} \right)^2}, \qquad (4)$$

subject to the constraint:

$$\sum_{i=1}^{p} |\Phi_i|^q \le c$$

where LASSO solves the penalized regression with q = 1. Smoothly convex penalties (for example, q = 2) produce shrinkages, as is the case with ridge regression. From the forecast error variance decomposition of the sparse VAR model, Demirer et al. (2018) compute the connectedness measures proposed by Diebold and Yilmaz (2012, 2014). These measures use the generalized VAR modeling framework proposed by Koop, Pesaran, and Potter (1996) and Pesaran and Shin (1998), hereinafter KPPS, to produce variance decompositions invariant to the ordering of the series. For H = 1, 2, ..., we denote the KPPS *H*-step-ahead forecast error variance decomposition as:

$$\theta_{ij}^{g}(H) = \frac{\sigma_{jj}^{-1} \sum_{h=0}^{H-1} (e_i' A_h \Sigma e_j)^2}{\sum_{h=0}^{H-1} (e_i' A_h \Sigma A_h' e_i)},$$
(5)

where  $\Sigma$  is the variance matrix of the error vector  $\varepsilon_t$ ,  $\sigma_{jj}$  is the standard deviation of the error of the *j*-th equation and  $e_i$  is a selection vector with value one at the *i*-th element and zero otherwise. As the sum of the elements of each row in Equation (5) is not equal to 1  $(\sum_{j=1}^{N} \theta_{ij}^{g}(H) \neq 1)$ , in order to obtain a unit sum of each row of the variance decomposition matrix, the following normalization has to be conducted for each entry:

$$\tilde{\theta}_{ij}^{g}(H) = \frac{\theta_{ij}^{g}(H)}{\sum_{j=1}^{N} \theta_{ij}^{g}(H)} \quad , \tag{6}$$

where by construction  $\sum_{j=1}^{N} \tilde{\theta}_{ij}^{g}(H) = 1$  and  $\sum_{i,j=1}^{N} \tilde{\theta}_{ij}^{g}(H) = N$ . Thus, Equation (6) constitutes a natural measure of the pairwise directional connectedness from firm/country *j* to firm/country *i*. Using the KPSS variance decomposition, the total spillover or system-wide connectedness can be represented by:

$$S^{g}(H) = \frac{\sum_{i,j=1}^{N} \tilde{\theta}_{ij}^{g}(H)}{\sum_{i,j=1}^{N} \tilde{\theta}_{ij}^{g}(H)} = \frac{\sum_{i,j=1}^{N} \tilde{\theta}_{ij}^{g}(H)}{N} \quad .$$
(7)

This spillover measure quantifies the contribution of the shocks of the energy firm/country i to the forecast error variance (Diebold and Yilmaz, 2009). Next, the total directional spillover received by energy firm/country i from all other energy firms/countries j is:

$$S_{i\leftarrow \circ}^{g}(H) = \frac{\sum_{j=1}^{N} \tilde{\theta}_{ij}^{g}(H)}{\sum_{i,j=1}^{j\neq i} \tilde{\theta}_{ij}^{g}(H)} = \frac{\sum_{j=1}^{N} \tilde{\theta}_{ij}^{g}(H)}{N} \quad .$$

$$(8)$$

Similarly, the total directional spillover from firm/country i to the other energy firms/countries j is:

$$S^{g}_{\circ \leftarrow i}(H) = \frac{\sum_{j=1}^{N} \widetilde{\theta}^{g}_{ji}(H)}{\sum_{i,j=1}^{j\neq i} \widetilde{\theta}^{g}_{ji}(H)} = \frac{\sum_{j=1}^{N} \widetilde{\theta}^{g}_{ji}(H)}{N} \quad .$$
(9)

Finally, the net spillover from firm/country i to the remaining energy firms/countries j is:

$$S_i^g(H) = S_{\circ \leftarrow i}^g(H) - S_{i \leftarrow \circ}^g(H) \quad . \tag{10}$$

Based on our two-step methodology, all spillover measures reflect shocks determined by idiosyncratic factors of the energy firms/countries and are unaffected by the systematic common factors.

## 4. Empirical results

#### 4.1. Effects of global common factors on energy stock returns

Figure 1 shows the amount of variance explained by each of the principal components associated with our original series, in decreasing order, at both country and firm levels. To implement the method proposed by Fan et al. (2021), we estimate Equation (1) by OLS regression for each time series of stock returns for either the country or firm, depending on whether the analysis is developed at the country or firm level. The regressors correspond to the *k*-first principal components. The selection criterion considers that the principal components must explain at least 50% of the stock returns variance. For this reason, for the country-level analysis, we used the first five principal components, which explain 52.01% of the returns variance, while for the firm-level analysis, the first 20 components were used, accounting for 51.03% of the variance. Our results are robust to variations of these numbers.

Figure 1. Principal components and variance proportion for energy stock returns

Figure 2a shows the Pearson correlations between energy stock markets at the country level. Two relevant facts stand out. First, in most cases we observe positive and significant correlations between energy stock markets. The markets of China and Vietnam show the lowest correlations. This indicates that among emerging countries the energy stock markets are closely integrated, which allows for contagion and risk spillovers and limits diversification opportunities within these markets. Second, in most cases the correlations between the energy stock markets of Sri Lanka, Mongolia and Bosnia-Herzegovina, on the one hand, and the other markets, on the other, present insignificant correlations. Initially, these results indicate that these markets allow risk diversification within the energy sector. Figure 3a shows similar patterns in the correlations between the energy stock returns at the firm level.

Residual stock returns, obtained following Equation (1), correspond to idiosyncratic components of countries and firms. Figures 2b and 3b show the correlations of the residual returns at the country and firm levels, respectively. These returns show lower correlations than those presented in Figures 2a and 3a, respectively. We conclude from visual inspection that non-idiosyncratic components in emerging energy stock markets play a prominent role in understanding diversification and risk transmission across markets.

4.2. Network comparison

Demirer et al. (2018) extend the methodology proposed by Diebold and Yilmaz (2012, 2014) using a LASSO-VAR model. This approach allows us to compute the connectedness measures using a high-dimensional data structure. In our case, we use a LASSO-VAR(1) model and consider a KPPS 10-week-ahead forecast error variance decomposition. At the country level, the spillover statistic for the energy stock returns of the total system is 61.43%, while for the idiosyncratic returns it falls to 24.45%. At the firm level, the corresponding spillover index is 82.97%, falling to 39.92% for energy returns once common global factors are taken into consideration. This finding reveals the importance of

the systematic and non-idiosyncratic common factors, which act as a channel that facilitates the transmission of shocks between energy stock markets.

Figures 4 and 5 present the spillover networks and matrices at the country level, corresponding to the forecast error variance decomposition of the whole system. Figure 4a shows that most of the energy stock markets are highly connected. The energy markets of Sri Lanka, Mongolia, Bosnia-Herzegovina and Montenegro are the least sensitive to shocks from other markets, followed by China, Vietnam, Pakistan, Peru, Argentina and Slovenia, which also receive relatively small shocks. At first glance, all these markets would allow highly diversified portfolios to be constructed in the energy sector, using stocks listed on the emerging markets. However, these possibilities are affected by the incidence of global common factors.

#### Figure 4. Spillover network at the country level

*Note:* Spillover network was computed through LASSO-VAR(1). Spillover statistics consider a KPPS 10-week-ahead forecast error variance decomposition. The size of the nodes represents the relative importance of the spillovers to other energy markets. Source: Authors' computation.

When these global factors are considered, the network based on residual stock returns presents a more dispersed structure (Figure 4b), which explains the lower spillover index (24.45%) and the lower linkages between most energy markets. Diversification opportunities should ideally be explored in the least connected markets within the network of idiosyncratic returns. The spillover matrix confirms these results, and indicates that few markets generate relevant idiosyncratic spillovers after controlling for global factors (Figure 5).

#### Figure 5. Spillover matrix at the country level

Note: Spillover matrix was computed through LASSO-VAR(1). Spillover statistics consider a KPPS 10-week-ahead forecast error variance decomposition. Source: Authors' computation.

We observed similar results at the firm level, although with a greater degree of heterogeneity within each country. Figure 6 depicts the spillover network between the 219 energy firms. This shows that the total spillover of the entire stock returns system was 82.97%, with 126 firms being net receivers of shocks and 93 net transmitters. The energy stocks of Chinese and Russian firms generate the largest spillovers (Figure 6a). The energy companies from Mongolia and Bosnia-Herzegovina do not experience significant spillovers with energy firms from other markets. Other markets, including those of South Korea, Thailand, Taiwan, Vietnam, Philippines, Sri Lanka, Pakistan, Montenegro, Argentina, Brazil and Peru are located in the periphery of the network and have more significant spillovers with relation to energy markets located in the core area of the network. In general, the firms of these countries are net receivers of shocks. Here again, these results are influenced by global common factors.

When we control for global non-idiosyncratic factors, the total spillover index falls to 39.92%. This, in line with what was observed at the country level, corroborates the relevance of non-idiosyncratic components for risk transmission. As occurred at the country level, the network of idiosyncratic components presents a more dispersed structure and less intense spillovers between firms (Figure 6b). In this case, 135 energy firms are net receivers of shocks and 84 are net transmitters. The periphery of the network is made up of companies from South Korea, Pakistan, Thailand, Taiwan, Vietnam, Philippines, Indonesia, Mongolia, Bosnia-Herzegovina, China, Czech Republic, Argentina and Brazil. Interestingly, the renewable energy firms show similar levels of connectedness to those shown by conventional energy firms within the same country.

#### Figure 6. Spillover network at firm level

*Note:* Spillover matrix was computed through LASSO-VAR(1). Spillover statistics consider a KPPS 10-week-ahead forecast error variance decomposition. The size of the nodes represents the relative importance of the spillovers to other energy firms. Source: Authors' computation.

#### 4.3. Diversification opportunities in the emerging markets energy network

The results discussed in the previous section reveal that non-idiosyncratic components of energy stock markets in emerging economies constitute an important amplification mechanism for international spillovers of risk. After removing the effect of the common factor structure, the effects of the idiosyncratic component of each country or market can be visualized (Barigozzi and Brownlees, 2019; Fan et al., 2021). This decomposition has direct implications for investment decisions since this component reflects the incidence of the specific qualities of the companies or markets, and it is completely diversifiable through energy stock portfolios.

Table 2 lists the 11 energy markets presenting the lowest spillovers received from other markets using the idiosyncratic returns. At the country level, the markets of Peru, Bosnia-Herzegovina, South Korea, Thailand, and Argentina stand out as being the least vulnerable in the network of emerging stock energy markets. They are followed by the markets of Malaysia, Colombia, Chile, Brazil, Indonesia and Russia. These countries are also characterized by transmitting somewhat smaller spillovers than those that they receive.

In line with Karim et al. (2022), we use the centrality<sup>1</sup> of each market to identify its position within the network. At the aggregate level, the markets in Table 2 present indicators that are lower than the median centrality of the entire system (20.0), which places them on the periphery of the market network. This, in addition to the low spillover effects they receive

<sup>&</sup>lt;sup>1</sup> Corresponding to the number of links related to each node (vertex), both incoming and outgoing from each node.

from the rest of the system, endow these markets with relevant diversification characteristics that can be exploited by international investors. Appendix 3 shows the spillovers and centrality statistics for all the countries.

Table 2. Energy markets with lowest level of connectedness in the network: *lowest* spillovers from others

spillovers from others										
Country	Spillover From	Spillover To	Net Spillover	Centrality						
Peru (PE)	7.94	6.36	-1.58	3						
Bosnia-Herzegovina (BH)	8.23	5.89	-2.34	3						
South Korea (KS)	10.13	8.86	-1.27	4						
Thailand (TH)	11.26	9.15	-2.12	7						
Argentina (AR)	11.37	9.12	-2.25	8						
Malaysia (MK)	12.61	10.62	-1.99	6						
Colombia (CO)	14.01	11.59	-2.43	10						
Chile (CL)	14.60	12.39	-2.21	11						
Brazil (BR)	15.96	13.74	-2.22	8						
Indonesia (IJ)	16.02	11.93	-4.09	15						
Russia (RU)	18.19	16.17	-2.02	18						

*Note:* Spillover effects computed from LASSO-VAR(1) and considering a KPPS 10-week-ahead forecast error variance decomposition. The total spillover of the system was 24.45% at the country level. Centrality corresponds to the number of links related to each node (vertex), both incoming and outgoing from each node. The median of the centrality measure was 20. Source: Authors' computation.

Table 3 lists the 35 companies with the lowest spillovers received from other emerging market energy companies. As with the results at the country level, these firms are the least vulnerable because they receive the least shocks from the system and transmit comparatively minor spillovers to other companies. In fact, almost two-thirds of these companies belong to the least vulnerable markets described in Table 2. However, greater heterogeneity can be seen between firms from different countries in addition to spillover effects of greater magnitude than those observed in the network at the country level. This shows that at the firm level, connectedness is more intense than that of the global network at the country level. Companies such as Kohinoor Energy Ltd. (Pakistan), Can Don Hydro Power and Vinh Son Song Hinh Hydropower (Vietnam), Sahacogen Chonburi Public Company Ltd. (Thailand) and Ultrapar Participacoes (Brazil) stand out as investment alternatives that favor portfolio diversification within emerging energy markets. Naturally, the firms described in Table 3 are located on the periphery of the network, corresponding to centrality indices lower than the median centrality of the entire system (13.0). See Appendix 4 for details on the centrality of all firms.

#### 4.4. Systemically relevant emerging markets and firms

Table 4 shows the energy markets with the largest spillovers transmitted to other countries, i.e., these markets have a greater systemic incidence on the global network of energy markets. In general, these markets present centrality indicators above the system median, placing them in the most central areas of the network. Markets such as Romania, India, Vietnam, Pakistan, Mongolia, Philippines, Hong Kong, Turkey, Montenegro, Sri Lanka and Taiwan transmit the most significant shocks to other emerging countries in the network. At the country level, it is evident that the markets described in Table 3 constitute relevant channels for international spillover risk transmission in emerging energy markets. Appendix 3 shows the spillovers and centrality statistics for all countries.

	and chergy markets m	the network. n	Shest spillerers	io onicis
Country	Spillover From	Spillover To	Net Spillover	Centrality
Romania (RM)	49.39	69.87	20.48	101
India (IN)	52.55	68.64	16.09	102
Vietnam (VM)	52.53	67.56	15.02	98
Pakistan (PK)	49.27	54.82	5.55	85
Mongolia (MG)	43.83	47.74	3.91	70

Taiwan (TW)	20.76	18.26	-2.50	20

 Table 4. Most relevant energy markets in the network: highest spillovers to others

*Note:* Spillovers effects computed from LASSO-VAR(1) and considering a KPPS 10-week-ahead forecast error variance decomposition. The total spillover of the system was 24.45% at the country level. Centrality corresponds to the number of links related to each node (vertex), both incoming and outgoing from each node. The median of the centrality measure was 20. Source: Authors' computation.

Table 5 shows the 35 energy companies with the highest spillovers to other markets. Two interesting points emerge that merit discussion. First, all these companies are net transmitters of shocks and, according to their centrality index, they are located in the core areas of the network. The magnitude of their spillovers, both transmitted and received, are greater than those observed in the network at the country level. For this reason, these energy firms can be said to facilitate the spread of risk between these energy companies at the global scale. Chinese (Huadian Power International Corporation, Huaneng Power International, China Petroleum & Chemical Corporation) and Brazilian companies (Centrais Eletricas Brasileiras, Petroleo Brasileiro, Centrais Eletricas Brasileiras, Companhia Energetica de Minas Gerais) stand out as relevant nodes in our network through which financial risk propagates. Second, there is a greater degree of heterogeneity in the identification of systemically important firms compared to that of countries. Less than a third of the systemically important companies indicated in Table 5 belong to the markets with the highest spillovers described in Table 4. Moreover, more than 50% of these firms belong to the less vulnerable and interconnected markets of the network. This reveals that a full network description, at the firm level, provides more detailed and useful information for investment decision making.

## 5. Conclusions and discussion

Previous studies of energy stock markets have considered market connectedness by using aggregate indices or by focusing solely on developed markets. Here, we have studied market connectedness using firm-level returns and by emphasizing the role of emerging markets in the global energy network. Methodologically, our study also differs from the previous literature insofar as we leverage recent advances in sparse VAR estimation within a time-series factor structure (see Fan et al., 2021). We separate the idiosyncratic from the non-idiosyncratic components of the energy stock returns, and estimate a network using the LASSO-VAR model, proposed by Demirer et al. (2018), to account for the high-dimensionality of our data.

Three main results emerge from our analysis. First, we show that emerging energy stock markets are closely integrated even after controlling for global energy factors. Moreover, the contribution of both systematic and idiosyncratic factors are clearly identified. The total cross spillover of our system at the country level is 61.43%, but once we filter out the non-idiosyncratic effects, this falls to 24.45%. At the firm level, the same procedure reduces total cross spillover from 82.97 to 39.92%. For this reason, we stress the importance of common systematic factors of asset prices for understanding energy market connectedness. In other words, global common factors largely determine shock transmission between energy firms in emerging markets. Nevertheless, our results also allow us to identify energy markets (and firms) that are able to generate high spillovers within the energy-finance system that are not related to systematic shocks. In summary, when monitoring emerging market energy companies, both for risk monitoring and portfolio pricing, systematic and idiosyncratic factors must be carefully considered in the lines proposed herein.

Closely related to this last point, we identify the least vulnerable markets and firms within the energy market network. These markets or firms are located on the periphery of the network and are less exposed to shocks from other markets or firms. Countries such as Peru, Bosnia-Herzegovina, South Korea, Thailand, Argentina, Malaysia, Colombia, Chile, Brazil, Indonesia and Russia offer important advantages for risk diversification. At the firm level, our results are more heterogeneous. Companies such as Kohinoor Energy (Pakistan), Can Don Hydro Power and Vinh Son Song Hinh Hydropower (Vietnam), Sahacogen Chonburi Public (Thailand) and Ultrapar Participacoes (Brazil) stand out as specific investment alternatives given their peripheral location in the global stock energy network for emerging markets.

Third, and finally, we identify markets and firms that are systemically important for global energy networks in emerging market finance. These markets or firms are the system's main net transmitters and tend to be located in the network's core area. The markets of Romania, India, Vietnam, Pakistan, Mongolia, Philippines, Hong Kong, Turkey, Montenegro, Sri Lanka and Taiwan are the most relevant in this sense. At the firm level, Chinese (Huadian Power International, Huaneng Power International, China Petroleum & Chemical) and Brazilian firms (Centrais Eletricas Brasileiras, Petroleo Brasileiro, Centrais

Eletricas Brasileiras, Companhia Energetica de Minas Gerais) have been identified as major transmitters of abnormally large shocks.

Appendix 3. Centrality index comparison at country-level.

*Notes:* Centrality degree corresponds to the number of links related to each node (vertex), both incoming and outgoing from each node. Residual returns were standardized using the conditional standard deviation calculated through a GARCH(1,1) model. Source: Authors' computation.

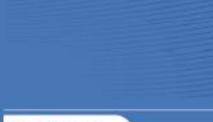

Appendix 4. Centrality index comparison at firm-level.
