Abstract: A new and easy synthesis of 2-arylethynyl-indole and 2-arylethynyl-pyrrole is described. N-deprotection and subsequent base-catalyzed elimination of N-tosylheteroaryl benzyl ketones are the key steps of the process.

Key words: acetylenes, indole, pyrrole, elimination, tosyl protecting group

The tosyl group has been one of the most commonly used groups to protect, activate and chelate indoles for lithiation at position 2. In the course of one of our synthetic programs, 1-tosyl-2-(p-methoxyphenylacetyl)indole (1a) was prepared in excellent yields starting from N-tosylindole by 2-lithiation, transformation of the resulting 2-lithio derivative into the 2-trimethylstannylindole derivative, and finally, Pd(0) catalyzed cross-coupling with p-methoxyphenylacetyl chloride (Scheme 1).

However, our attempts at the N-detosylation of 1a to obtain the indolyl ketone 2a using KOH in MeOH–H₂O or in THF–H₂O were unsuccessful: short reaction times only furnished starting material, and stronger conditions, longer reaction times and/or higher temperatures led to degradation. When the reaction was run in DMF with KOH at 80 °C, an unexpected product was formed. The ¹H-NMR of the product showed the characteristic shifts of 2-indolyl and p-methoxyphenyl rings, the absence of the tosyl group, and, surprisingly, the absence of the methylene singlet characteristic of 2a. The lack of benzylic protons suggested that another transformation had occurred in addition to N-deprotection. Moreover, no ketone absorption signal was observed by IR. The mass spectrum (MS = 247) of the purified product indicated loss of one molecule of H₂O and loss of the tosyl group in relation to the starting material 1a. The aforementioned data, combined with the observation of two quaternary carbons at δ 92.5 and 80.4 ppm in the ¹³C-NMR spectrum of the compound, led us to identify it as 2-(4-methoxyphenylethynyl)-1H-indole (3a).

A literature search for dehydrations of phenyl benzyl ketones to yield bisarylacetylenes only provided a few examples, all of which shared a common synthetic
pathway: transformation of the ketone into an enol derivative with a good O-substituted leaving group, followed by basic elimination to give the bisarylacetylene. No precedent was found for this type of reaction with N-tosyl-2-indolyl ketones as substrate, encouraging us to investigate the scope and limitations of this new route to aryl-heteroaryl-acetylenes, which are versatile synthetic intermediates for the preparation of bioactive natural compounds.

We envisaged transformation of 1a into 3a via two possible mechanisms, both of which imply O-activation of the enolate 4 followed by elimination, but which differ in their respective leaving groups. Hence enolate 4 could react with DMF to give an enol formiate (Scheme 2, a) that loses both the tosyl group and potassium formiate by KOH. Alternatively, intramolecular O-tosylation of 4 to provide indole-deprotection and the enol-leaving group intermediate could also lead to 3 (Scheme 2, b).

To discriminate between both mechanisms and investigate the importance of the N-tosyl group and/or the reaction solvent, several experiments were carried out using the two sets of ketones shown in Figure 1. The set 1 contains the model (1a), heteroaryl benzyl ketones without the tosyl protecting group (1b and 1c), aryl benzyl ketones (1d and 1e), and the aryl ketone 1f. The set 2 contains the N-tosylheteroaryl benzyl ketones 1g-m that differs in the heterocycle (pyrrole or indole) and in the substituents on the benzyl ring.

The N-tosyldindolyl ketones 1g-m were obtained using the same method as that for compound 1a, indicated in Scheme 1. However, the method did not work for p-nitrophenylacetamide chloride. Thus, ketones 1n-o were synthesized by direct condensation of the 2-lithioheterocycle with the acid chloride. Finally, ketones 1b and 1c, with unsubstituted pyrrole and N-methylindole, were prepared by direct acylation of the heterocycle using AlCl₃ or Et₂AlCl as catalysts, the latter of which provided for a more facile work-up.

The results of the study are summarized in Table 1. Ketones 1b-f, which do not contain an N-tosyl group, were treated with KOH in DMF under similar conditions to those used for 1a. In all cases, the starting material was recovered after 1-3 h of reaction, whereas decomposition compounds (entries 2-6) were obtained with longer reaction times. Compound 1f was used to test if increasing the acidity of the α-protons favours enolate formation and/or subsequent formylation. Again, the starting material was recovered after 24 h of reaction at 80 ºC. These results were the first indication of the importance of the N-tosyl group (Scheme 2, b) for the success of the reaction.

Treatment of pyrrolyl ketone 1g with KOH in DMF afforded pyrrolylacetylene 3g (entry 7) in only 19% yield, whereas use of a stronger base (NaH) increased the yield to 93% (entry 8). To determine if this stark improvement was general, ketone 1a was reacted with NaH in DMF. Acetylene 3a (entry 9) was thus obtained in 82% yield, underscoring the importance of the base. The ketones 1g-o are N-tosylheterocycles that differ in their respective heterocyclic rings and in their phenyl substituents: compounds 1a and 1g-i have electron-donating groups, compounds 1l-o have electron-withdrawing groups, and 1j-k have unsubstituted phenyl rings. The ketones 1g-m were reacted with NaH in DMF to give the acetylenes 3g-m in good to excellent yields (entries 7-15). In contrast, reaction of

![Scheme 2](image-url)
the ketones 1n and 1o, which have the strongest electron-withdrawing substituents, gave the ketones 2n and 2o, respectively, and did not lead to any substantial amount of the desired acetylene derivatives (entries 16, 17). Treatment of 1n and 1o with KOH in DMF afforded the deprotected ketones 2n and 2o in 96% and 58% yield, respectively (entries 18, 19). The results obtained for the p-nitrobenzyl ketones could be imputed to the strongly electron-withdrawing nitro group, which decrease the nucleophilicity of the enolate and favours
nucleophilic attack on the sulphonyl group to produce the deprotection.

<sup>a</sup>: reaction time was determined by monitoring consumption of the starting material by TLC.
<sup>b</sup>: longer reaction times led to decomposition products.

These results clearly showed the importance of the N-tosyl group for acetylene formation. We then assayed the reaction of 1a with NaH in several solvents to rule out a mechanism in which the enolate reaction is solvent dependent (Scheme 2, a). Dimethyl sulfoxide (DMSO), N,N-dimethylacetamide (DMA), dichloromethane (DCM), N-methyl-2-pyrrolidone (NMP), and dimethox-
yethane (DME) were thus evaluated as solvents. The experiments were done at 80 ºC, and monitored by HPLC after 3 and 5 h. Only starting material was observed when DCM and DME were used as solvent, but 3a was produced using DMSO (product isolated in 64% yield), NMP (54%), and DMA (37%) after 5 h of reaction.

Conclusion

In summary, a new procedure for the synthesis of arylethynyl heterocycles has been developed. The procedure comprises heating heteroaryl ketones—readily obtained in good yields—with NaH in DMF. The 1-tosyl-2-heteroaryl ketone general structure is essential for the elimination step, as none of the ketones lacking a tosyl group (1b-1f) provided the corresponding acetylenes. The acetylene formation is not solvent-dependent. Notwithstanding, DMF was the highest yielding solvent tested for the formation of acetylene 3a, followed by DMSO, NMP and DMA.

Reagents and solvents were purified according to Purification of Laboratory Chemicals. Melting points (Mp) were determined using a Büchi Melting Point B540 in open capillaries and are uncorrected. 1H-NMR and 13C-NMR spectra were recorded on a Varian Mercury 400 MHz spectrometer in automatic mode. Multiplicity of the carbons was assigned using DEPT and gHSQC experiments. Multiplicities of 13C and 1H-NMR are indicated with the usual abbreviations according to off-resonance (13C-NMR) decoupling: (s) singlet, (d) doublet, (t) triplet, (q) quadruplet, and also, for 1H-NMR, (m) multiplet and (bs) broad singlet. Spectra were referenced to an appropriate residual solvent peak (CDCl3). IR spectra were obtained on a Thermo Nicolet FT-IR spectrometer. HRMS were performed on an Agilent LC/MSD-TOF high resolution mass spectrometer using ESI-MS ionization in positive/negative mode by the Mass Spectrometry Service of the University of Barce-

lona. All starting ketones were prepared in our laboratory except 1d-f, which were purchased from Aldrich.

General procedure for the preparation of the ketones 1a and 1g-o

To a solution of N-tosylindole (108 mg, 0.4 mmol) in dry THF (5 mL) at -78 ºC, was added BuLi (2.5 M in hexane, 176 µL, 0.4 mmol) dropwise. The solution was stirred for 30 min at low temperature, and then trimethyltin chloride (1 M in THF, 440 µL, 0.4 mmol) was added. The mixture was allowed to reach room temperature. After 2 h, the solution was quenched with sat. aq. KF (5 mL). The organic phase was separated, dried over anhyd. MgSO4, filtered, and concentrated under vacuum. The tin derivative was then diluted in dry toluene (5 mL) and added to a solution of 4-methoxyphenylacetyl chloride (128 µL, 0.8 mmol) in dry toluene (5 mL). PdCl2(PPh3)2 (28 mg, 0.04 mmol) and CuI (15 mg, 0.08 mmol) were then added, and the mixture was refluxed for 16 h. After cooling, the crude was washed with sat. aq. NaHCO3 (3 x 20 mL) and brine (20 mL), dried over anhyd. MgSO4, filtered, and concentrated under vacuum. Purification by flash chromatography on silica gel (95:5 hexane/EtOAc) afforded the ketone 1a as a yellow solid (115 mg, 65%); mp (MeOH) 117-119 ºC.

13C-NMR (CDCl$_3$): $\delta = 185.3$ (s), 144.9 (s), 135.6 (s), 132.9 (s), 132.8 (s), 132.7 (s), 130.7 (d), 130.5 (d), 129.3 (d), 128.7 (d), 128.4 (d), 124.1 (d), 110.4 (d), 45.6 (t), 21.7 (q).

General procedure for the preparation of ketones 1n and 1o. Preparation of N-Tosyl-2-(4-nitrophenylacetyl)indole (1n)

A solution of N-tosylindole (444 mg, 1.6 mmol) in dry THF (5 mL) was cooled to −78 ºC, and t-BuLi (1.7 M in hexane, 1.1 mL, 1.8 mmol) was added dropwise. The reaction mixture was stirred for 30 min, and then 4-nitrophenylacetyl chloride (659 mg, 3.3 mmol) was added dropwise. The solution was allowed to reach room temperature, and stirring was maintained for 3 h. The crude was quenched with sat. aq. NH$_4$Cl (5 mL) and extracted with EtOAc (3 x 5 mL). The organic phase was
dried over anhyd. MgSO\(_4\), filtered, and concentrated under vacuum. Purification by flash chromatography on silica gel (85:15 hexane/EtOAc) afforded In as a yellow solid (479 mg, 67%); mp (MeOH) 162-167 °C.
