45 **ABSTRACT:**

46

47 The characterization of a decanuclear FeIII cluster with  $\alpha$ -methyl-2-pyridinemethanolate, generated by  
48 the hydrolysis of Schiff bases, inspired us to carry out an initial exploration of the direct syntheses of  
49 medium nuclearity FeIII clusters starting from aldehydes in methanolic medium. The new complexes  
50 exhibit an unprecedented  $\{\text{Fe}_{10}(\mu_3\text{-O})_8\}$  cluster core.

51

52

53 Clusters containing oxo-bridged FeIII cations have been widely studied due to their biological relevance  
54 as mimics of iron storage proteins or in the search for Single Molecule Magnet (SMM) responses. The  
55 oxo bridges between FeIII cations give usually antiferromagnetic interactions that allow low or zero spin  
56 ground states. However, high ground spin states, exhibiting slow relaxation of magnetization, can be  
57 stabilized for some topologies like Fe4 iron-stars or Fe8 clusters, which are among the earlier and best  
58 studied SMM families.<sup>1–5</sup>

59 2-(Hydroxymethyl)pyridine (Hhmp) is a classic ligand that has been largely employed in CuII, NiII and  
60 MnII,III,IV cluster chemistry (more than 250 entries in the CCDC database) but, in contrast, its  
61 reactivity with FeIII is limited to some scarce Fe2, Fe4, Fe6, and Fe8 and one Fe9 complexes<sup>6–10</sup>  
62 mainly reported by Christou and Brechin, while polynuclear derivatives of the chiral related ligand,  
63 HMehpm ( $\alpha$ -methyl-2-pyridinemethanol), are unprecedented in FeIII chemistry.

64 The condensation reaction between an aldehyde and an amine to produce a Schiff base can be reversed  
65 by hydrolysis to give the starting reagents, usually helped by its coordination to polarizing cations, as  
66 FeIII is. The metal assisted nucleophilic attack of a methoxide on the carbonyl C-atom of the  
67 coordinated aldehyde yields the hemiacetal methoxy(pyridine-2yl)methanolato (MeO-hmp<sup>–</sup>) ligand.  
68 This ligand is chiral, but the reaction is not selective and produces the (R)/(S)-MeOhmp<sup>–</sup>racemic  
69 mixture. This reaction is well known in organic chemistry but in cluster chemistry it has been reported  
70 in very few cases by the deliberate or accidental reaction of 2-pyridinecarboxaldehyde and methanol,<sup>11–</sup>  
71 <sup>17</sup> due to the breaking of Schiff bases and subsequent reaction of the aldehyde<sup>18–20</sup> or due to an  
72 unexpected oxidation of Hhmp.<sup>21</sup> Noteworthy, coordination of MeO-hmp<sup>–</sup> to iron cations has been  
73 observed only one time in a mononuclear FeII complex and in one mixed FeIII LnIII complex.<sup>19,20</sup> The  
74 reaction of the neutral L1 Schiff base (obtained by condensation of 2-pyridylaldehyde with 1,2-  
75 diphenyl-ethylenediamine, Scheme 1) with ferric nitrate and sodium thiocyanate in methanolic medium  
76 allows us to characterize the decanuclear cluster [Fe10(MeO-hmp<sup>–</sup>)8( $\mu$ 3-O)6( $\mu$ 3-OH)2(NO3)6(NCS)2]  
77 (1) or [Fe10(MeO-hmp<sup>–</sup>)8( $\mu$ 3-O)7( $\mu$ 3-OH)(NO3)7] (2) in the absence of thiocyanate. The exclusive  
78 presence of MeO-hmp<sup>–</sup> ligands suggests the complete hydrolysis of L1 and further reaction of the  
79 aldehyde with the solvent according to Scheme 1. To check this hypothesis, the direct reaction of ferric  
80 nitrate, sodium thiocyanate and 2-pyridinecarboxaldehyde in basic methanolic solution was tried,  
81 yielding the same complex 1 or complex 2 in the absence of thiocyanate, proving that the aldehyde was  
82 the intermediate reagent in the formation of the decanuclear cluster.

83 In the light of the reproducibility of 1 and 2 by direct syntheses, we explored the direct reaction with  
84 several aldehydes that allowed us to characterize the core of the [Fe10(MeO-3Mehmp<sup>–</sup>)8( $\mu$ 3-O)4( $\mu$ 3-  
85 OH)4(NO3)8]<sup>2+</sup> cluster starting in this case from 3-methyl-2-pyridinecarboxaldehyde. This set of  
86 reactions proves for the first time that this synthetic strategy is a convenient way to obtain high  
87 nuclearity FeIII clusters. Synthetic details are provided in the ESI.† IR and powder X-ray spectra are  
88 shown in Fig. S1 and S2.†

89 The structures of 1–3 show a common core that consists of ten FeIII cations in an octahedral  
90 environment and sixteen bridging O-donors, Fig. 1. Crystallographic details and selected bond distances  
91 and angles are summarized in Tables S1–S4.† The core contains eight  $\mu_3$ -O/ $\mu_3$ -OH bridges and eight  $\mu$ -  
92 O bridges which are provided by the O-alcoxo arms from eight MeO-hmp<sup>–</sup> ligands. The remaining  
93 coordination sites are occupied by six nitrate ligands and two thiocyanates for 1 and only mono or  
94 bidentate nitrate ligands for 2 and 3.

95 Four FeIII cations (Fe1, Fe3, Fe5 and Fe7 for 1 and 2 or Fe(1) and symmetry related for 3, Fig. S4†) link  
96 two bidentate MeO-hmp<sup>–</sup> ligands each and show a FeN<sub>2</sub>O<sub>4</sub> environment. The MeO-hmp<sup>–</sup> ligands are  
97 chiral but four of them correspond to the (R)-enantiomer and the other four to the (S)-enantiomer. The  
98 iron cations linking (R)-ligands show a  $\Delta$  conformation, whereas the iron cations linking (S)-ligands  
99 exhibit a  $\Lambda$  conformation, showing the expected transference of chirality from the ligand to the cation  
100 environment, Fig. S5.†

101 Fe4, Fe8, Fe9 and Fe10 for 1 and 2 or Fe(3) and symmetry related for 3 have a FeO<sub>6</sub> environment  
102 formed by one O-alcoxo, three  $\mu_3$ -O and one bidentate nitrate ligands, whereas the apical Fe2 and Fe6  
103 cations are linked by two O-alcoxo, two  $\mu_3$ -O, one N-thiocyanate and one monodentate nitrate ligands,  
104 resulting in a FeNO<sub>5</sub> environment for 1, by one bidentate and two monodentate nitrates for 2 and by two  
105 monodentate nitrates for the case of 3, resulting in FeO<sub>6</sub> environments, Fig. 2. The inner {Fe<sub>10</sub>(O)<sub>8</sub>}  
106 core of the clusters is defined in all the cases by  $\mu_3$ -O and  $\mu_3$ -OH donors which are linked by means of a  
107 strong H-bond with the monodentate nitrate ligands. The Fe–N<sub>py</sub> and Fe–O<sub>nitrate</sub> bond distances take  
108 large values, up to 2.226 Å, whereas the Fe-( $\mu_3$ -O/OH) distances are much shorter with values reaching  
109 1.85 Å.

110 The ten FeIII cations determine a rare polyhedron with exclusively triangular faces, which is  
111 unprecedented in cluster chemistry. The most common distortion of a cube bicaugmented on two  
112 opposite faces (the elongated square bipyramid Johnson solid J15) consists of the rotation of the  
113 opposite apical faces to produce the classical gyroelongated square bipyramid (Johnson solid J17),  
114 which can be alternatively described as a bicaugmented square antiprism, Scheme 2, left.

115 This regular deltahedron has 16 faces, 24 edges and 10 vertexes with configuration  $2 \times 34; 8 \times 35$ . The  
116 new polyhedron reported in this work is also derived from the J15 polyhedron but distorted by the  
117 displacement of two opposite pairs of edges of the central cube in opposite directions, Scheme 2, right.

118 The resulting polyhedron also has 16 faces, 24 edges and 10 vertexes but with configuration  $6 \times 34; 4 \times$   
119  $36$  related by an S<sub>4</sub> improper symmetry axis. The {M<sub>10</sub>( $\mu_3$ -O)<sub>8</sub>} inner core, which is shown in Scheme  
120 2, is unprecedented in cluster chemistry and the search in the CCDC database shows that it can only be  
121 found as a fragment of two larger Fe<sub>14</sub> clusters which have the S<sub>4</sub> edge, ESI Fig. S6.† 22,23 The  
122 topological analysis with TOPOS<sup>24,25</sup> describes the new {M<sub>10</sub>( $\mu_3$ -O)<sub>8</sub>} core as 4,4,6M<sub>10</sub>-1.

123 The room temperature  $\chi_{MT}$  product for 1–3 ranges between 12.47 and 14.8 cm<sup>3</sup> mol<sup>–1</sup> K which is  
124 much lower than the expected value for ten isolated FeIII cations (43.75 cm<sup>3</sup> mol<sup>–1</sup> K), suggesting a  
125 very strong antiferromagnetic coupling, Fig. 3. The  $\chi_{MT}$  value decreases continuously upon cooling,

126 tending to zero at low temperature. The large number of low-lying spin states, partially populated even  
127 at low temperature, makes difficult the observation of the  $\chi_M$  maxima but for 2, a susceptibility  
128 maximum at 6 K was reached, evidencing unambiguously the  $S = 0$  ground state. The size of the cluster  
129 and the large number of superexchange pathways exclude the calculation of the  $J$  coupling constants and  
130 prevent the fit of the experimental data. This drawback has been overtaken by the fact that the  
131 interactions mediated by Fe–O–Fe bridges have been widely studied and their strong dependence on the  
132 bond angles and on the Fe–O distances has been well established: the antiferromagnetic interaction  
133 increases for large bond angles and short distances and empirical expressions to evaluate the magnitude  
134 of the superexchange have been proposed by different authors.<sup>26–28</sup>  
135 Magnetostructural semiempirical correlations (MSCs) have been recently proposed by Christou et al.<sup>28</sup>  
136 to predict the  $J$  values ( $2J$  Hamiltonian,  $\text{cm}^{-1}$ ) for the interactions promoted by Fe–O–Fe bridges as a  
137 function of the mean Fe–O distances and the corresponding bond angle, according to the expression:

$$J = 1.23 \times 10^3 \cdot (-0.12 + 1.57 \cos \phi + \cos^2 \phi) \cdot \exp(-8.99 \cdot r).$$

138  
139  
140  
141 In our case all the FeIII cations of the inner  $\{\text{Fe}_{10}(\mu_3\text{-O})_8\}$  core are linked among them by 16 Fe–O–Fe  
142 bridges with bond angles comprised between  $129.5^\circ$  and  $121.6^\circ$  and short Fe–O distances that induce  
143 strong AF interactions. The double Fe–O–Fe bridges involving the lower  $\mu_3\text{-O}$  angle and the alcoxido  
144 donor of the MeO-pym<sup>-</sup> ligands show angles around  $100^\circ$  and, consequently, a poorly efficient  
145 superexchange pathway that does not compete with the interactions promoted by the  $\mu_3\text{-O/OH}$   
146 pathways. The MSC calculated  $J$  values for the representative complex 1 are shown in Fig. 4, left. These  
147 interactions are cooperative and determine the antiparallel alignment of five up and five down local  
148 spins which are consequently related among them by a  $S_4$  symmetry, Fig. 4 right.

149

150 **CONCLUSIONS**

151

152 As a conclusion, we report here the initial exploration of a new synthetic route to obtain high nuclearity  
153 FeIII clusters generated by the in situ reaction of pyridylaldehydes with alcohols. The reported Fe10  
154 complexes 1–3 show the largest nuclearity of the FeIII/pyridyl-alcoxo family, exhibiting a new  
155 {M10( $\mu$ 3-O)8} core. The complete study of this new synthesis strategy starting from different  
156 counteranions, cations and co-ligands will be reported in a future paper.

157
