ABSTRACT

Many breast cancer survivors (BCS) suffer the consequences of antineoplastic treatments that induce a hypoestrogenic state, leading to chronic climacteric symptoms as the genitourinary syndrome of menopause (GSM), arousing significant alteration in their quality of life (QoL).

Non-hormonal therapies (NHT) are first line treatments, safe but with mild efficacy. When facing a moderate-severe GSM, the options to BCS are limited, finding: local estrogen therapy (ET), considered the “gold standard” but with concerns about security; vaginal androgens and prasterone, that seems to trigger an activation of estrogen and androgens receptors of the vaginal epithelium layers, without activating estrogen receptors on other tissues, being potentially safe but still without strong evidence in favor for BCS; vaginal lasers, which appear to improve vascularization of vaginal mucosa by stimulating the remodeling of the underlying connective tissue, but with contradictory results of its efficacy in recent randomized clinical trials; and ospemifene, an oral selective estrogen receptor modulators (SERM) presenting mild vaginal estrogenic potency and anti-estrogenic effect at the endometrial and breast level, but still not recommended for its use in BCS in recent North American Menopause Society (NAMS) guidelines. There is a need to further studies evaluating objectively efficacy and safety of these

1
2
3 promising therapeutic options. On the other hand, sexuality must be seen as a multifactorial
4
5 issue, where the GSM is only a part of the problem, evidence shows that sexual counselling
6
7 improves the QoL of BCS.
8
9

10 Finally, there is a need to limit the underdiagnosis and undertreatment of GSM in BCS, the
11
12 primary goal of BCS treating physicians regarding this issue, have to be the provision of
13
14 information of what to expect regarding genital and sexual symptoms to BCS.

1. INTRODUCTION

Overall survival of women who suffer breast cancer (BC) is increasing over the last decades [1], and many of breast cancer survivors (BCS) will receive antineoplastic treatments that may affect their ovarian function or anti-estrogenic treatments [2]. These drugs induce a hypoestrogenic state that usually lead to chronic climacteric symptoms and arousing significant alteration in their quality of life (QoL) that may drive to discontinuation on the adjuvant therapies [3-6].

One of the main complaints of hypoestrogenism is the vulvovaginal atrophy (VVA), which is included in the new concept of genitourinary syndrome of menopause (GSM) [7]. This syndrome, that comprises from genital symptoms as dryness, burning, and irritation, to sexual and urinary symptoms, have a great impact on the quality of life (QOL). It affects up to 50% of postmenopausal women [8], and even more frequently in young patients who receive anti-estrogenic or antineoplastic drugs [9]. Often, these symptoms are under-diagnosed and under-treated due to underreport from the patients and the limited awareness from professionals [10]. And more importantly, if this appeared GSM receive not treatment, worsens over time [11].

Since in many cases BCS suffer from hormonal tumors, they have limited therapeutic strategies to treat GSM. Non-hormonal therapies (NHT) are first line treatments, safe but with mild efficacy and usually with a short-term improvement [12]. When facing a moderate-severe GSM, local estrogen therapy (ET) is considered the "gold standard" therapy for general population, but in respect to BCS, there are concerns about security, particularly due to the possible increased recurrence risk (RR) if systemic absorption occurs [13].

In the recent years new therapeutic options are appearing on the board, such as vaginal laser (VL), ospemifene and androgen local therapy (AT), that could be useful alternatives for those patients where ET are not recommended. Up to date, there is no consensus on how to treat moderate-severe GSM in BCS [14].

1
2
3 The aim of this review is to summarize the current evidence on GSM therapeutic options for BCS
4
5 and its main future challenges.
6
7

8 **2. CURRENT STRATEGIES**

9

10
11 At this moment, most of BCS suffering from GSM are not yet diagnosed and therefore are not
12
13 receiving any treatment. Of those which are treated, most are receiving first line therapies based
14
15 on NHT [15].
16
17

18 **3.1 Non-Hormonal Therapies**

19

20
21 The first line treatments for mild-moderate GSM, according to the international guidelines, are
22
23 NHT. Therefore, these are also the first line treatments in BCS [16]. Within NHT, generally
24
25 comprise moisturizers mainly based on water or vegetable oil. However, these compounds do
26
27 not reverse atrophy nor improve vaginal epithelium characteristics; thence, the observed
28
29 improvement is temporary and short-term. In a specific BCS systematic review the 85% of the
30
31 trials found on this systematic review described short term efficacy; with a 30 days follow-up or
32
33 less, and present low risk of potential side effects regarding safety [14].
34
35
36
37

38 **2.2 Vaginal oestrogen**

39

40
41 Since hypoestrogenism is the cause of GSM, the most reasonable treatment would be one based
42
43 on estrogen, which have proved to be the most effective, since directly eliminate the cause of
44
45 the atrophy. [17].
46
47

48
49 However, there are concerns in the literature regarding the possible systemic absorption of
50
51 vaginal estrogen in BCS. Systemic estrogen administration may increase the risk of breast cancer
52
53 recurrence [18] and is generally not advised for survivors of breast cancer, although hormone
54
55 therapy use may be considered in women with severe vasomotor symptoms unresponsive to
56
57
58
59
60

1
2
3 nonhormone options, with shared decision-making in conjunction with their oncologists [16-
4
5 19].

6
7
8 Vaginal estrogen absorption is variable, this absorption appears to decrease once there is
9
10 improvement in vaginal mucosae [20], but still the use of low dose vaginal estrogen treatment
11
12 is accepted if there is no improvement using non-hormonal treatments in BCS suffering GSM
13
14 [16-19]. Different methods of vaginal estrogen administration appear to be equivalent, being
15
16 estriol preparations the most usually used, which is a weak action estrogen (Table 1).
17
18

19
20 Therefore, there is some reluctance to use local estrogen therapy in BCS among oncologists,
21
22 showing in a specialist study that up to 70% of oncologists dealing with BCS do not prescript
23
24 hormone therapies. Mainly due to fear of interferences with adjuvant treatments that may
25
26 result in an increased BC recurrence risk [15].
27
28

29
30 In respect of estrogen use in BCS, recent systematic reviews show clear controversy on this topic,
31
32 finding trials evaluating short follow-up cohorts of BCS not showing increased recurrence after
33
34 local estrogen use [21], and conversely, recent prospective designed studies suggesting that the
35
36 use of vaginal estrogen therapy may increase levels of estrogen serum levels [22].
37
38

39
40 From our point of view, further studies are needed, controlling confounding factors as variability
41
42 of vaginal estrogen absorption, and given the controversy, it is recommended to explain risks
43
44 and benefits, individualizing each case with oncologists before using local estrogen therapies on
45
46 BCS.
47
48

49 **3. PROMISING STRATEGIES**

50 **3.1 Vaginal androgens and prasterone**

51
52
53 Other options as intravaginal androgens or pre-androgens are getting attention as a potential
54
55 treatment for GSM in BCS, since androgen receptors have been identified in the vaginal mucosa.
56
57
58
59
60

1
2
3 Local androgenic administration at vaginal level of testosterone cream or local pre-androgenic
4
5 prasterone, seems to trigger an activation of estrogen and androgens receptors of the vaginal
6
7 epithelium layers, without activating estrogen receptors on other tissues due to the lack of
8
9 aromatase at this level [23, 24]. A recent pilot study evaluating Dehydrixyepiandrosterone
10
11 (DHEA) or prasterone was conducted in BCS receiving aromatase inhibitors, observing that
12
13 serum estradiol was not increased after 6 months of 6.5 mg prasterone every 48h and
14
15 presenting GSM improvement [25]. But further studies with bigger sample size are needed to
16
17 document the long-term safety of this treatment.
18
19
20
21

22 Table 1.
23
24

25 **3.2 Vaginal Lasers**

26
27

28 The vaginal laser is nowadays a hot topic in GSM treatment, that appears to improve
29
30 vascularization of vaginal mucosa by stimulating the remodeling of the underlying connective
31
32 tissue, which enlarges the vaginal epithelium and allows it to accumulate glycogen. Due to the
33
34 accumulation of glycogen the vaginal flora is restored, the vaginal pH is reduced, and symptoms
35
36 of GSM improve [26].
37
38
39

40 Up to date, we can find three different non-surgical energy-based: fractional microablative CO₂
41
42 laser, erbium-YAG laser and temperature-controlled radiofrequency. Initial literature strongly
43
44 suggested that the vaginal laser therapy with either the erbium- laser or the CO₂ laser was an
45
46 effective therapeutic option to treat GSM symptoms, but recent randomized clinical trials [RCT]
47
48 evaluating objective outcomes have brought some caution to conclude its efficacy and safety in
49
50 BCS, since there is a lack of data about BC recurrence and serum estradiol levels were not tested
51
52 [27, 28].
53
54
55

56 In 2018 FDA published an alert highlighting that the efficacy and safety of treatments had not
57
58 been established. Warning the risk of serious adverse events to the patient when using laser and
59
60

1
2
3 thermal energy devices used for a range of vaginal symptoms including those related to
4
5 menopause [29].
6
7

8
9 Despite this alert, a huge increase of published papers regarding the use of vaginal laser for GSM
10
11 shows that vaginal laser is been often used as a therapeutic option in the clinical practice, even
12
13 without strong evidence recommending its use. There is a need for clinical assays evaluating the
14
15 efficacy and security for this therapy in BCS [30].
16
17

18 **3.3 Ospemifene**

19
20
21 Ospemifene is an oral selective estrogen receptor modulators (SERM), presenting estrogenic
22
23 and antiestrogenic effect depending on the tissue where its action takes place. It presents mild
24
25 vaginal estrogenic potency with capacity to improve the GSM symptoms in a similar way to local
26
27 estrogenic therapy, and also improves bone mineral density. On the other hand, seems to have
28
29 an anti-estrogenic effect at the endometrial and breast level, for this reason, appears to be a
30
31 promising therapy for BCS [31-33].
32
33
34

35
36 In 2013, FDA approved the use of ospemifene for dyspareunia and vaginal dryness, but it is not
37
38 recommended for its use in BCS in recent North American Menopause Society (NAMS)
39
40 guidelines [34].
41
42

43 **3.4 Sexual counseling**

44
45
46 Taking into consideration the relevance of psychosocial aspects in the sexual health of patients,
47
48 some studies have evaluated the use of educational strategies and counselling as a treatment
49
50 of sexual dysfunction (SD) in BCS [35]. Evidence shows that the sexual health of these women
51
52 improves with educational interventions specifically focused on sexual aspects, as well as with
53
54 couple therapy enhancing the communication of SD aspects and cancer. Unfortunately,
55
56 specialized sexual assessment is not usually performed according to a recent review evaluating
57
58 sexual dysfunction in BCS [36].
59
60

4. MAIN CHALLENGES

4.1 Underdiagnose and undertreatment

The main challenge of GSM in BCS is still the underdiagnose and the undertreatment, that prevent the access of many patients to therapies that may significantly improve their daily quality of life. The primary goal of BCS treating physicians regarding this issue, have to be the provision of information of what to expect regarding genial and sexual symptoms in the process of BC treatments, and the early diagnose and treatment of GSM.

4.2 Efficacy and Safety assessment of therapeutic options

Nonetheless, given the current focus on GSM in BCS, there is a need of strong evidence regarding efficacy and safety of the therapeutic options that are appearing on the board, to provide information and best quality options to our patients.

In 2003, the FDA issued a guide outlining possible endpoints for studies assessing topical estrogen to treat GSM: change in severity of symptoms, change in vaginal pH, and change in vaginal maturation index (VMI). But since then, the majority of the studies are still using subjective outcomes such as Vaginal Health Index (VHI), visual analogue scale (VAS) of GSM symptoms and the female sexual function index (FSFI). Instead, not many of the considered objective outcomes such as the VMI are used in the recent literature assessing GSM [37].

There is a need of objective outcomes to test efficacy and compare the new therapeutic options. Some authors have studied vaginal epithelial thickness, composition of the lamina propria, and vaginal compliance as future alternatives [38].

4.3 Sexological approach

1
2
3 The prevalence of sexual dysfunction in BCS oscillate between 40-80%, and vulvovaginal health,
4 directly linked to sexual health, is a key factor for female pleasure, but the treatment of this
5 condition is not always related to an improvement of the SD, since sexuality must be seen as a
6 multifactorial issue, where the GSM is only a part of the problem.
7
8
9

10
11
12 The main symptoms of SD reported by BCS include insufficient lubrication and penetration pain,
13 but also difficulties in arousal or excitation, decreased sexual desire and body image impairment.
14

15 A recent observational study showed greater SD rate in BCS who receive aromatase inhibitors,
16 presenting greater impairment of sexual desire, arousal, lubrication, orgasm, satisfaction and
17 dyspareunia compared to healthy population, as well as lower scores in FSFI [39].
18
19
20
21
22

23 Evidence shows that BC has the highest rates of lost disability-adjusted life years (DALYs) among
24 all types of cancer; being SD one of the main reasons of this problem. Breast cancer survivors
25 regardless of age, BC stage and ongoing treatment, are concerned about the possible impact of
26 BC treatments on sexual function and are interested in maintaining a good sexual life [40, 41].
27
28
29
30
31
32

33 Therefore, a combination of a physical treatments and sexual counseling approach, through
34 validated questionnaires and sexual interviews would provide a deeper and more accurate
35 strategy for treating GSM in BCS.
36
37
38
39
40

41 42 **5. CONCLUSION**

43
44
45 GSM is the leading cause of sexual dysfunction in BCS and severely limits the quality of life of
46 these patients. The first line treatment in BCS presenting mild-moderate GSM is always using
47 non-hormonal therapies, which appear to be safe but present a limited efficacy and short-term
48 effect. In cases of GSM in BCS refractory to non-hormonal treatment, the next step should
49 include a shared decision-making process centered on patient's expectations and needs, as well
50 as with the oncology team evaluating risks and benefits. Alternatives such as local estrogen
51 therapy, local androgen therapy, vaginal laser or ospemifene could be considered, always with
52
53
54
55
56
57
58
59
60

1
2
3 the patient's awareness of whether there are discrepancies in the data found on the efficacy
4 and safety of all of them. In those BCS with GSM mainly affected by sexual complaints a
5 biopsychosocial sexual approach including sexual counselling should also be offered. High
6 quality clinical studies assessing its efficacy and safety in terms of serum estradiol raise
7 evaluation or relapse evaluation are still lacking in BCS.

For Peer Review Only

| Study / Year | n | Design | Follow up | Participants | Intervention | Outcomes | Hormonal adjuvant Therapy | Receptor status (ER+) | Results | Conclusion |
|---|-----------------------|---|-----------|--|---|--|--|--------------------------------|--|---|
| Kendall et al. Annals of Oncology, 2005 ⁴² | 7 | Prospective before-after analysis | 12 weeks | Patients on adjuvant AI therapy for BC | Estradiol 25mg daily for 2 weeks | Measure estradiol | All women with AI. anastrozole. letrozole or exemestane | Not reported. | 2-week analysis: 83% estradiol rise. 10 weeks: 66% E rose 83% improved clinical status | Anastrozole seems to better control estradiol elevation when treated with VET |
| Pfeiler et al. Climacteric, 2011 ⁴³ | 6 | Prospective before-after analysis | 4 weeks | Patients on adjuvant AI therapy for BC | 0.5mg vaginal estriol daily for 2 weeks. | Estradiol, FSH and LH serum levels. Clinical improvement (VAS). | All women receiving anastrozole. | All women | No change in estradiol. Increased FHS and LH. Clinical improvement in 83%. | Increase in FHS and LH may indicate systemic estradiol effects. |
| Wills et al. Journal of Oncology practice, 2012 ¹³ | 24 BCS 24 Controls | Prospective clinical study | 12 weeks | Patients on adjuvant AI therapy or SERM for BC | Vaginal Estradiol 25ng | E2 serum levels | All women with SERM or AI | Women with ER+ or high risk BC | E2 levels were significantly greater in VET group than in controls. | VET treatment increases E2 levels. Should be used with caution. |
| Donders et al. Breast Cancer Res Treat, 2014 ²² | 16 | Open label bicentric phase I pharmacokinetic study. | 12 weeks | Patients on adjuvant AI therapy for BC | 0.03mg Estriol + Lactobacillus. | Estradiol (E2), Estrone (E1), estriol (E3) serum levels. Clinical improvement (VAS). | All women with AI. letrozole or anastrozole. | All women | No change in E1 and E2. Small transient increase in E3. Clinical improvement in 100%. | E3 + Lactobacillus is safe in BC patients and improves symptoms. |
| Melisko et al. JAMA Oncology, 2016 ⁴⁴ | 76 | Randomised non-comparative study | 12 weeks | Patients on adjuvant AI therapy for BC | Estradiol ring 7.5ng vs. Testosterone cream at 1% concentration: 1.5mg/week | E2 serum levels VHI | All women with AI | All women | Transient E2 increase in 11% Estradiol group and 12% TST group. Persistent E2 rise in 0% Estradiol group and 12% TST group. Sexual improvement in both groups. | Transient increase in E2 that finally reached normal levels. Meets the primary safety endpoint. |
| Whiterby et al. The Oncologist, 2011 ⁴⁵ | 21 | Phase I/II pilot study Before-After study | 8 weeks | Patients on adjuvant AI therapy for BC | TST cream for 28 days 300/150ng | E2 and TST levels. Clinical improvement. | All women with AI. | Not reported. | E2 levels remained suppressed Symptom improvement. | They demonstrate clinical efficacy and tolerance. |
| Mension et al. Cimacteric, 2022 ²⁵ | 10 | Prospective clinical study | 6 months | Patients on adjuvant AI therapy for BC | 6.5 mg/d of DHEA. use one ovule every night, during the first month, and one ovule every two nights, for the entire 5 resting months. | E2 serum levels FSFI | All women with AI. anastrozole. letrozole or exemestane. | All women. | E2 remained under safety levels Symptom improvement. Sexual improvement | Prasterone meets the primary safety endpoint and demonstrate clinical efficacy and tolerance. |

TABLE 1. Estrogen plasma levels after local therapy with sexual steroids.

ER: Oestrogenic Receptors, VET: Vaginal Oestrogenic Therapy, BC: Breast Cancer, AI: Aromatase inhibitors, E: Oestrogen, FSFI: Female Sexual Function Index, VVA: Vulvovaginal Atrophy, TST: Testosterone, VAS: Visual Analogue Scale.
